GENERAL INFORMATION

CARCINOGENESIS ABSTRACTS makes available abstracts, annotations or citations of significant carcinogenesis articles collected from the current major biomedical sources of world literature. This service is provided by the National Cancer Institute through a contract with The Franklin Institute Research Laboratories for preparation of the publication, under Contract No. NOI-CP-75885 with the National Cancer Institute, U.S. Department of Health, Education and Welfare. Published and distributed by The Franklin Institute PressSM.

SUBSCRIPTIONS

For sale by The Franklin Institute Press, Box 2266, Philadelphia, PA 19103. Subscription rate for Volume 17, consisting of 12 monthly issues and a cumulative index, is \$90.00 U.S., Canada and Mexico and \$120.00 foreign. Individual issues will be charged at \$10.00 to subscribers, \$15.00 each to non-subscribers. Check should be made payable to The Franklin Institute Press.
Maruzen Co., Ltd., 3-10, Nihonbashi 2-Chome, Tokyo 103, Japan, is the exclusive distributor of CARCINOGENESIS ABSTRACTS in Japan.

GENERAL INFORMATION

CARCINOGENESIS ABSTRACTS makes available abstracts, annotations, or citations of significant cancer articles collected from the current major biomedical sources of the world literature. This service is provided by the National Cancer Institute through a contract with Franklin Research Center for preparation of the publication.

FREQUENCY OF PUBLICATION: *CARCINOGENESIS ABSTRACTS*, Volume 17, is published in 12 monthly issues with indexes, plus a cumulative index.

ABBREVIATIONS

JOURNAL names are abbreviated according to the *List of Journals Indexed in Index Medicus, Abbreviation Listing*. If the journal is not listed in this, abbreviations are derived from the *International List of Periodical Title Word Abbreviations*.

LANGUAGE of the article is indicated in parentheses after the title and is represented by a three-letter code. The source for these codes is *MARC Manuals Used by the Library of Congress*, pages 183-187.

ABBREVIATIONS used in abstracts:

A	angstrom(s)	mOsm	milliosmolar
ACTH	adrenocorticotrophic hormone	max	maximum
ADP	adenosine diphosphate	mEq	milliequivalent(s)
AMP	adenosine monophosphate	min	minute(s)
ATP	adenosine triphosphate	ml	milliliter(s)
approx	approximately	μl	microliter(s)
av	average	mm	millimeter(s)
BCG	bacillus Calmette-Guerin	mo	month(s)

LIBRARY OF L. URBANA - CHICAGO

REVIEW

- 79-4801 ICPEMC Publication No. 2. Advice on Screening of Chemicals for Mutagenicity. (Eng) Matter, B. (Verte Rive, Lausanne, Switzerland); Kilbey, B. J.; Drake, J.; Hollaender, A.; Ramel, C.; Ray, V.; Sundaram, K. *Mutat Res* 64(3): 155-158; 1979.

Available screening tests for gene mutations include systems involving bacteria, fungi, drosophila, and cultured mammalian cells. In vivo or in vitro cytogenetics, the micronucleus test, and the dominant lethal test are used to detect chromosome damage, and evidence for primary DNA damage is obtained from bacterial repair tests, DNA repair tests in mammals, and assays for sister-chromatid exchanges, gene conversion, and mitotic recombination. The two main limitations of screening tests are the restricted spectrum of genetic damage any one test can detect and the failure of some systems to provide for metabolic conversion of compounds. (4 refs)

- 79-4802 Quantum Studies Probe Biological Molecules. (Eng) Rawls, R. L. (No affiliation given.) *Chem Eng News* 57(27): 20-21; 1979.

Improved methods for ab initio quantum mechanics provide chemists with clues to the reactivity of drugs, carcinogens, teratogens, and some biomolecules. Families of potential carcinogens, such as the benzopyrenes, are being studied to determine a structural property or set of properties that will indicate carcinogenic activity. One scientist is comparing the properties of molecules in benzopyrenes as they are metabolized to proximate and ultimate carcinogens. (no refs)

- 79-4803 Carcinogenicity Testing for Control of Environmental Tumor Development in Man. (Eng) Berenblum, I. (Weizmann Inst. Science, Rehovot, Israel). *Isr J Med Sci* 15(6): 473-479; 1979.

Rather than waiting until a new form of environmental cancer becomes clinically recognized before trying to determine its cause, high priority is now given to routine carcinogenicity testing of the various products to which humans are exposed. Carcinogenicity tests carried out in vivo are time-consuming and technically very demanding. To be reliable, these tests require an elaborate set of conditions. Short-term tests were devised primarily for preliminary screening and, possibly, to replace the laborious animal tests. Although the Ames mutagenicity

assay is not ideal, it is 90% accurate and is a notable advance in the search for rapid screening of large numbers of compounds. In this assay, the mammalian liver extract does not necessarily contain the appropriate enzyme system for all classes of carcinogens. The in vitro transformation of mammalian cells seems promising, but it needs further refinement and trials before it can be put to practical use as a routine method of carcinogenicity testing. There are several difficulties inherent in extrapolating from the results of experimental tests to humans. Apart from the problem of false positives and false negatives, there are difficulties of interpretation. This is due to differences in species, strain, organ response, etc, and also to the fact that carcinogenesis is a multistage process and subject to strong influences by cocarcinogenic factors. These factors include precarcinogens, oncogenic viruses, promoting agents, and miscellaneous factors operating in conjunction with suboptimal doses of physical, chemical, or viral carcinogens. Additional procedures are needed to detect these associated factors. (29 refs)

- 79-4804 Recommendations on Data Production and Analysis Using the Salmonella/Microsome Mutagenicity Assay. (Eng) de Serres, F. J. (Natl. Inst. Environmental Health Sciences, P.O. Box 12233, Research Triangle Park, NC 27709); Shelby, M. D. *Mutat Res* 64(3): 159-165; 1979.

Points and components of the protocol for the Ames Salmonella/microsome plate assay that could contribute to variations in results are emphasized, and recommendations are made as to where and how the protocol should be modified for use in routine mutagenicity testing. Problems in data presentation and analysis were also addressed. (3 refs)

- 79-4805 An Overview of the Problem of Thresholds for Chemical Carcinogens. (Eng) Truhaut, R. (Faculte des Sciences Pharmaceutiques, 4 Avenue de l'Observatoire, 75006 Paris, France). *IARC Sci Publ* (25): 191-202; 1979.

According to a current view, it is impossible to establish safe levels for carcinogens, because there are no thresholds for their action. This concept is supported by the arguments that (1) cancer may result from a mutation in a somatic cell; (2) the cancer cell is self-replicating; (3) with some carcinogens, the primary carcinogenic effects of any

individual dose persist and remain irreversible during the life-span of the animals, finally resulting in a tumor; (4) a lasting change is induced by one tumor-initiating event; and (5) cancer can occur in response to chemicals, even in single doses, long after their disappearance from the body. Arguments against this theory include the following: (1) every organism has a limited life-span, and, thus, has a real threshold; (2) the probability of a carcinogen reaching a single cell is lowered with minute doses; (3) a carcinogen-induced alteration of a molecular target can be repaired; (4) there is a difference between malignant cellular transformation (first stage of malignancy) and the clonal development of a transformed cell, which produces a cancer; clonal development is affected by certain host-defense reactions, and the threshold may result from what happens at that stage; (5) certain chemically induced tumors induce immunological, tumor-associated rejection reactions; (6) epidemiological studies indicate the existence of a threshold for certain exogenous carcinogenic factors (ie, cigarette smoking); (7) experimental studies indicate that thresholds exist for various carcinogens; and (8) some carcinogens give rise to tumors only after inducing particular pathologic changes. No-effect levels should be determined by long-term investigations of the effects of low levels in animals similar to humans in their metabolic potential and sensitivity. Human exposure to all chemical carcinogens should be reduced to the feasible minimum. (27 refs)

- 79-4806 The Role of Laboratory Animal Studies in Estimating Carcinogenic Risks for Man. (Eng) Rall, D. P. (Natl. Inst. Environmental Health Sciences, P.O. Box 12233, Research Triangle Park, NC 27709). *IARC Sci Publ* (25): 179-189; 1979.

Data from the first 16 volumes of the International Agency for Research on Cancer monograph series are analyzed in order to determine the extent to which biological responses to chemicals in laboratory animals predict those in humans. It has been shown that if there is strong evidence that a chemical is carcinogenic in appropriate laboratory animals, it must be treated as if it were carcinogenic in humans. Further evidence supporting this conclusion is presented. According to data in the monographs, there is considerable evidence that chemicals that are carcinogenic in laboratory animals are carcinogenic in humans, providing qualitative predictability, and there is tentative evidence of a quantitative relationship between the amount of a chemical that is carcinogenic in animals and the amount that is carcinogenic in humans. (3 refs)

- 79-4807 Statement Regarding OSHA's Proposed Federal Cancer Policy. (Eng) Jukes, T. H. (Div. Medical Physics, Univ. California, Berkeley, CA 94720). *Clin Toxicol* 14(1): 133-139; 1979.

The proposed Occupational Safety and Health Administration (OSHA) Federal Cancer Policy is reviewed and its validity discussed. The Policy is considered unscientific and unworkable. The 'no-threshold' concept, extending to single molecules, is biologically unsound, as is the rationale for disposing of the list of 'natural' carcinogens. The OSHA Statement ignores the concept of time as it relates to the dose-response relationship of carcinogens, as well as the concept of probability. The validity of testing for human carcinogens in experimental animals is also questionable. It is necessary to know, rather than guess, that a mouse test will positively identify a substance as a human, and not just a rodent, carcinogen. The cancer hazard for occupational exposure to 'industrial' carcinogens would be considerably reduced by the elimination of cigarette smoking, which should be OSHA's first objective. It is inaccurate to say that increases in cancer related to certain carcinogens are 'not yet observable' since the latency period is related to the dosage to which one is exposed. Finally, the statement that benign tumors are equally as important as malignant tumors is erroneous and unacceptable. (12 refs)

- 79-4808 The Carcinogenicity of Vinyl Chloride. (Eng) Gričute, L. (Unit Environmental Carcinogens, International Agency Res. Cancer, Lyon, France). *IARC Sci Publ* (22): 3-11; 1978.

Data on the carcinogenicity of vinyl chloride (VC) are summarized. Chronic exposure of laboratory animals to VC produces hepatic lesions and bone changes similar to those described in humans. In the first animal study implicating VC as a carcinogen, rats were exposed to 30,000 ppm VC, 4 hr/day, 5 days/wk, for 9-12 mo. They developed auditory sebaceous gland tumors and osteochondromas. Inhalation exposure in rats, mice, hamsters, and rabbits produced angiosarcomas of the liver and other organs and malignant tumors of the lung, intestine, kidney, skin, mammary gland, and forestomach. VC is carcinogenic in rats at 25 and 50 ppm in air and in mice and hamsters at 50 ppm in air. Ingestion of VC by gavage (50.0 and 16.6 mg/kg/day for 52 wk) produced liver angiosarcomas and other tumors in rats, but 3.3 mg/kg/day produced angiosarcomas at sites other than the liver. Transplacental administration of VC to rats between days 12 and 18 of gestation produced angiosarcomas. The in vitro mutagenicity of VC to bacteria is greatly enhanced by liver tissue homogenates from humans, mice, and rats. Chloroethylene oxide is considered to be the main active carcinogenic metabolite of VC; it is a strong alkylating agent that is responsible for mutagenesis in bacteria, yeast, and Chinese hamster cells. VC produces chromosome alterations in human lymphocytes. Primary liver angiosarcoma is the tumor observed in workers in the polyvinyl chloride (PVC) industry. This tumor is extremely rare in the general population, and those detected in PVC workers represent a 400-fold increase over the expected incidence. It is not known whether VC induces other tumors in humans. The av latent period

between initial VC exposure and liver angiosarcoma diagnosis is 20 yr. (34 refs)

- 79-4809 Ethylene Oxide: Toxicology Review and Field Study Results of Hospital Use. (Eng) Glaser, Z. R. (Div. Criteria Documentation and Standards Development, Natl. Inst. Occupational Safety and Health, Rockville, MD 20857). *J Environ Pathol Toxicol* 2(5, Special): 173-207; 1979.

Ethylene oxide (ETO) is used extensively within health care facilities to sterilize equipment and supplies. Recent results of mutagenesis tests have increased the concern for potential health hazards associated with exposure to ETO. Data from a National Institute for Occupational Safety and Health (NIOSH) report, in which evidence for the toxic effects of ETO, especially its mutagenic, teratogenic, and carcinogenic potentials, was assessed, are presented. Additionally, a limited field survey was conducted by NIOSH to document the use, problems, and potential for human exposure in medical facilities. Based on this review, measures for the control of occupational exposure have been recommended. The report includes a summary of the airborne ETO concentrations measured within health care facilities. NIOSH estimates that there are >10,000 ETO sterilizers in use in US health care facilities and that approx 75,000 workers are potentially exposed to ETO in these facilities. Reasons for the unnecessary exposure of personnel were found to include improper or inadequate ventilation of sterilizers, aerators, and working spaces; improper handling and/or storage of sterilized items; untrained workers operating some sterilization equipment; improper operating techniques leading to mishandling of some ETO sterilizing equipment; poor design of the sterilization facility; and design limitations of the sterilization equipment. (130 refs)

- 79-4810 Asbestos-enhanced Uptake of Carcinogens (2 Letters to Editor). (Eng) Light, W. G. (Technology Development Dept., Walden Div., Abcor, Inc., 850 Main St., Wilmington, MA 01887); Lakowicz, J. R.; Hylden, J. L.; Bevan, D. R. *Nature* 279(5711): 349-350; 1979.

The previously reported increased rate of transfer of benzo(a)pyrene (BP) adsorbed to particulate silica or amosite asbestos, compared with BP in a microcrystalline form, is suggested to result principally from adsorption of mobile dipalmitoyl L- α -phosphatidylcholine vesicles onto the particulate surface, rather than from increased solubilization of BP in an aqueous state. The preferential interfacial transfer of carcinogens to cell membranes and/or lung surfactant at the particulate surface may be an important factor in cocarcinogenesis. The first authors defend their conclusion concerning increased solubilization of BP by virtue of its association with particulate materials. (5 refs)

- 79-4811 Environmental Intoxicants and Their Fundamental Interactions. (Eng) Eisinger, J. (Bell Labs., Murray Hill, NJ 07974); Blumberg, W. E. *Q Rev Biophys* 11(4): 429-437; 1978.

Diseases of environmental origin and their role in an industrial society are reviewed. The manifestations of adverse environments can be divided into two groups: (1) widely distributed environmental conditions (ie, asbestos, aflatoxin, zeolite, and polycyclic aromatic hydrocarbons and (2) environmental health disasters that result from heavy exposure of a localized population to a toxic environment (ie, lead, methyl mercury, and chlorinated dibenzo-p-dioxins). The first group is generally associated with a low incidence of disease. The related health problems are difficult to trace and often are not recognized. (24 refs)

- 79-4812 Community Air Pollution in Canada: A Review and Predictions for the 1980's. (Eng) Bates, D. V. (Dept. Health Care and Epidemiology, Univ. British Columbia, 2075 Wesbrook Mall, Vancouver, British Columbia, V69 1W5, Canada). *Can Med Assoc J* 120(10): 1252-1256; 1979.

Changes in the most commonly measured air pollutants in Canada since nationwide air sampling began in 1971 are reviewed. The major pollutants include sulfur dioxide, suspended particulates, and nitrogen dioxide and ozone. Other pollutants considered are arsenic, which has been linked to lung cancer, and asbestos, which has been linked to pleural mesothelioma. There is increasing worry about community air pollution in cities with large metal-fabricating plants, and community exposure to asbestos fibers is likely to be of concern in the 1980's. (17 refs)

- 79-4813 Chemically Induced Occupational Cancer. (Ger) Heese, B. (Bayerische Akademie für Arbeits- und Sozialmedizin, Pfarrstrasse 3, 8000 Munich 22, W. Germany). *Munch Med Wochenschr* 97(18): 837-838,855; 1979.

Data on industrial chemical carcinogens are reviewed briefly. Arsenic, soot, tar, asbestos, aromatic amines, radiation, benzene, nickel, chromium-containing dust, dichlorodimethyl ether, chlorodimethyl ether, and vinyl chloride are the major industrial carcinogens. (no refs)

- 79-4814 The Carcinogenicity of Lead. (Eng) Moore, M. R. (Dept. Medicine, Gardiner Inst. Medicine, Western Infirmary, Univ. Glasgow, Glasgow G11 6NT, Scotland); Meredith, P. A. *Arch Toxicol* 42(2): 87-94; 1979.

A review of the carcinogenic potential of lead in man is presented. Lead is known to have specific effects on the cytochrome P450 system in animals and man and thereby to depress the mixed function oxidase system; thus lead may conceivably influence the potential carcinogenicity of many compounds. Animal studies have provided evidence of the carcinogenicity of lead by itself. Studies in rats with lead phosphate and lead acetate are described. Many of the studies have led to inconclusive results. The possible mechanisms for the carcinogenic effect of lead compounds are discussed briefly. Human studies have relied on geographic associations and industrial studies. The variations in cancer mortality rates in different areas in the world have been investigated; however, there are so many variables to consider that it is difficult to select those which are truly correlated with cancer. Various industrial studies of workers exposed to various lead compounds have provided no evidence to suggest that exposure to lead salts causes cancer of any site in man. Since the kidney is responsible for lead excretion during periods of excessive exposure, it was thought that an increase in kidney tumors would be observed; however, no such association was seen. The animal studies indicate considerable species and sex differences in the carcinogenicity of lead, and human studies have not proven that lead causes cancer in man. (71 refs)

- 79-4815 Environmental Causes of Cancer in Childhood. (Eng) Miller, R. W. (Epidemiology Branch, NCI, Bethesda, MD 20014). *Adv Pediatr* 25: 97-119; 1978.

Several environmental agents that cause cancer have short enough latent periods so that exposure and the diagnosis of neoplasia occur within the pediatric age-span. In other instances, the neoplasm occurs during adulthood but originates from prenatal or childhood exposures. Exposure to ionizing radiation has been linked with childhood acute leukemias and chronic myelogenous leukemia, thyroid tumors, and breast cancer. Ionizing radiation poses some cancer risk no matter how small the dose. Asbestos exposure during childhood (1) induces mesothelioma in adulthood and (2) may potentiate the capacity of cigarette smoking later in life to induce lung cancer. Potential transplacental carcinogens include alkylating agents, benzene, immunosuppressants, phenacetin, diethylstilbestrol, and diphenylhydantoin. The possibility of a leukemogenic effect should be considered when cytotoxic agents are used to treat children likely to be long-term survivors of their malignant or nonmalignant disease. Other chemical agents include anabolic androgenic steroids, immunosuppressants, polyvinyl chloride, and dietary contaminants. With respect to viruses and leukemia, a variety of hypotheses has been tested concerning the vertical or horizontal transmission of leukemia, especially in children, but none has been proved. Viruses have been associated with Hodgkin's disease, Burkitt's

lymphoma, nasopharyngeal carcinoma, and carcinoma of the uterine cervix. Concepts about the viral etiology of cancer have had to be adapted to fit observations in children concerning candidate viruses. Genetic influences and their interactions with radiation, viruses, and chemicals are also reviewed. (130 refs)

- 79-4816 The Mutagenicity of Trimethylphosphate. (Eng) Connor, T. H. (Univ. Texas Medical Branch, Galveston, TX). *Mutat Res* 65(2): 121-131; 1979.

The mutagenicity of trimethylphosphate (TMP), a fuel additive, industrial chemical, and flame retardant, is reviewed. TMP can produce a variety of genetic damage in many diverse systems. However, this damage is usually only manifested at relatively high doses. The overall acute and chronic toxicity of TMP is low. In a National Cancer Institute carcinogenicity study, rats received up to 300 mg/kg/wk and mice received up to 1,500 mg/kg/wk by gavage for 2 yr. TMP induced adenocarcinomas of the uterus/endometrium in the female mice (18%-38% incidence) and benign fibromas of the sc tissue in the male rats. There was no evidence of an increased tumor incidence in other tissues or organs in these animals. At high doses, TMP produces temporary sterility in mice, rats, rabbits, and *Drosophila* and dominant lethal effects in several mouse strains. The latter included increases in early fetal deaths and preimplantation losses that coincided with the postmeiotic stages of spermatogenesis. TMP produces a weak mutagenic effect in different microbial systems. It is concluded that TMP is a relatively weak mutagen in most systems although it produces a wide range of genetic damage, most probably due to its methylating capacity. (33 refs)

- 79-4817 Cyclophosphamide in Chronic Active Hepatitis (Letter to Editor). (Eng) Althouse, R. (Unit Chemical Carcinogenesis, International Agency Res. Cancer, Lyon, France); Huff, J. E.; Tomatis, L.; Wilbourn, J. D. *Br Med J* 1(6178): 1630-1631; 1979.

There are at least 64 case reports of cancer (mostly leukemias, lymphomas, and bladder cancers) in patients treated with cyclophosphamide for a variety of malignant and nonmalignant diseases. This drug also causes cancer in mice and rats when administered in doses similar to those used in clinical practice. The few epidemiological studies suggest that over a period of 10 yr, between 5% and 15% of patients treated with alkylating agents will develop cancer. (8 refs)

- 79-4818 Drug Safety: Phenacetin (Letter to Editor). (Eng) Macklin, A. W. (Wellcome Res. Labs.,

3030 Cornwallis Road, Research Triangle Park, NC 27709); Welch, R. M.; Cuatrecasas, P. *Science* 205(4402): 144-148; 1979.

Previous assertions supporting the view that phenacetin (PA) is a carcinogen are criticized. Numerous negative feeding studies of PA are cited: a 2-yr study in Sprague-Dawley rats (20-200 mg/kg/day), a 31-mo study in Berlin-Druckery rats (>100 mg/kg/day), an 18-mo study in C57BL/6 mice (up to 754 mg/kg/day), studies in Fischer 344 rats and B6C3F1 mice (500 mg/kg/day), and two studies in dogs (20-450 mg/kg/day for up to 30 mo). The methodology of the previously cited positive animal studies is criticized. The processing of the pelleted diets involved temperatures beyond the melting point of PA. At these high temperatures, reactive N-oxidation products can be formed, and chemical reactions between dietary components and degradation products of PA might occur. One diet contained fish meal, a product that contains N-nitroso compounds and relatively large amounts of secondary amines and is often preserved with nitrites. Other reactions between degradation products of PA might occur in the acidic environment of the upper gastrointestinal tract. Po treatment of animals with N-hydroxyphenacetin, a urinary metabolite of PA that is unstable and is able to form azo and nitroso compounds under the acid or alkaline conditions of the gastrointestinal tract, is not a valid assay. PA has not been demonstrated to be mutagenic with or without metabolic activation, and it does not efficiently nitrosate under physiological conditions. (28 refs)

79-4819 Hazardous Nitrite (Letter to Editor)? (Eng) Clelland, R. C. (Dept. Statistics, Wharton Sch., Univ. Pennsylvania, Philadelphia, PA); Bowers, E. J. *Chem Eng News* 57(28): 4; 1979.

The contention that the use of low levels of nitrite for preserving cured meats is a carcinogenic hazard is criticized. Although numerous references to linear extrapolations from extremely high dosage levels can be found in the literature, citations showing that feeding realistic diets containing properly cooked bacon and other meat products, cured with 40-120 ppm sodium nitrite, to experimental animals has resulted in detrimental health effects are lacking. In addition, nitrite and nitrate are synthesized in the human intestine and are routinely present in amounts >140 ppm. Nitrite is also a normal constituent of green vegetables and human saliva. (no refs)

79-4820 The Organic Chemistry of N-Nitrosamines: A Brief Review. (Eng) Anselme, J. P. (Dept. Chemistry, Univ. Massachusetts at Boston, Harbor Campus, Boston, MA 02125). *ACS Symp Ser* (101): 1-12; 1979.

The structure, synthesis, and reactions of N-nitrosamines,

particularly the N,N-dialkyl- and N,N-aryl-nitrosamines, are reviewed. (59 refs)

79-4821 Stereochemical Effects on N-Nitrosamine Chemistry. (Eng) Lyle, R. E. (Chemistry Dept., North Texas State Univ., Denton, TX 76203); Fribush, H. M.; Singh, S.; Saavedra, J. E.; Lyle, G. G.; Barton, R.; Yoder, S.; Jacobson, M. K. *ACS Symp Ser* (101): 39-56; 1979.

The electronic arrangement of the nitrosamine function provides an interesting stereochemical consequence which may be as significant in the biochemistry of nitrosamine metabolism as in their chemistry. This review of stereochemical effects on N-nitrosamine metabolism includes conclusions concerning the electronic interaction and the electronic structure of the nitrosamine that can be drawn from its physical properties. (29 refs)

79-4822 Oxidative Activation of N-Nitrosamines: Model Compounds. (Eng) Michejda, C. J. (Chemical Carcinogenesis Program, NCI Frederick Cancer Res. Center, Frederick, MD 21701); Kroeger-Koepeke, M. B.; Koepeke, S. R.; Kupper, R. J. *ACS Symp Ser* (101): 77-84; 1979.

Studies designed to contribute to an understanding of how nitrosamines are activated to produce the reactive electrophilic intermediates that interact with cellular components to elicit a carcinogenic response are reviewed. (26 refs)

79-4823 N-Nitrosamine Fragmentation and N-Nitrosamine Transformation. (Eng) Loeppky, R. N. (Dept. Chemistry, Univ. Missouri-Columbia, Columbia, MO 65211); Gnewuch, C. T.; Hazlitt, L. G.; McKinley, W. A. *ACS Symp Ser* (101): 109-123; 1979.

The fragmentation and transformation reactions of N-nitrosamines are reviewed. The nitrosation of 1-substituted aziridines illustrates that tertiary amine nitrosation can occur by elimination or substitution on the nitrosaminium intermediate. When a product of this reaction, nitrosaminoacetate, is treated with 50% aqueous ethanol, a cleavage reaction occurs, yielding benzylbutylnitrosamine and benzaldehyde. This cleavage reaction is a general property of β -hydroxynitrosamines, (β -HNA's), and a preliminary review of work in this area is given. Impetus for this work was provided by the fact that several β -HNA's are prevalent environmental contaminants and by the possibility that this type of cleavage reaction could potentiate or diminish the carcinogenicity of these nitrosamines. The base-catalyzed cleavage of β -HNA's

produces a smaller fragment nitrosamine and a carbonyl compound. The nitrosamine products obtained by treating β -HNA's with potassium tert-butoxide in tetrahydrofuran are tabulated. The rates of cleavage for a number of different β -HNA's are given. The mechanism of the base catalysis in this transformation reaction is currently under investigation and is not completely understood. Several significant side transformations of the reaction are illustrated. The possible relevance of base-catalyzed transformations of nitrosamines to nitrosamine carcinogenesis is reviewed, with emphasis on the fact that there have been few reports of chemical alterations that change the carbon skeleton of the nitrosamine. (23 refs)

- 79-4824 Carcinogenic Nitroso Compounds in Food Products. (Rus) Arkhipov, G. N. (Inst. Nutrition, Moscow, USSR); Zhukova, G. F.; Pimenova, V. V. *Vopr Pitan* (2): 12-21; 1979.

Literature pertaining to the level of carcinogenic nitroso compounds in food products is reviewed. Analysis of foods by chromatography, fluorometry, spectrophotometry, and mass spectrometry showed that the highest levels of nitroso compounds are found in processed meat and fish (up to 207 $\mu\text{g/kg}$). (95 refs)

- 79-4825 Laboratory Animal Feed (Letter to Editor). (Eng) Knapka, J. J. (Veterinary Resources Branch, Div. Res. Services, NIH, Bethesda, MD 20205). *Science* 204(4400): 1367; 1979.

A previous study in which a high nitrosamine (NA) concentration (52 ppb) was found in a sample of National Institutes of Health (NIH) laboratory animal feed may have tested the effects of manufacturing procedures on NA stability rather than NA concentrations in specific diets. This sample was also the only complete diet tested that was not subjected to a manufacturing process involving heat treatment. In addition, only a single bag was sampled. More recent studies of samples taken from different batches of the NIH diet have revealed NA concentrations ranging between 1.1 and 6.4 ppb. The fish meal used in the diet formulation contained up to 172 ppb volatile NA's. (7 refs)

- 79-4826 α -Amino Nitrite Esters and Their Analogues: Possible Reactive Intermediates in N-Nitrosamine Formation? (Eng) Keefer, L. K. (Analytical Chemistry Section, Lab. Carcinogen Metabolism, NCI, Bethesda, MD 20014). *ACS Symp Ser* (101): 91-108; 1979.

It is postulated that α -dialkylamino nitrite esters are involved as intermediates in a number of nitrosamine-forming

reactions of interest in environmental carcinogenesis. These species are proposed to fragment to nitrosamines and carbonyl compounds by way of intramolecular interaction between the nucleophilic amino function and the electropositive nitrosyl nitrogen atom. The fact that a variety of seemingly diverse transformations can be mechanistically unified by invoking this pathway is taken as evidence that α -dialkyl nitrosamines do in fact have at least transitory existence. (29 refs)

- 79-4827 Nitrosamines from Pesticides. (Eng) Oliver, J. E. (Beltsville Agricultural Res. Center, Beltsville, MD 20705). *Chemtech* 9(6): 366-371; 1979.

Certain nitrogen-containing pesticides, as residues in soil, water, plants, etc, may be nitrosated by indigenous nitrite or by other nitrosating agents--eg, nitrogen oxides from automobile exhausts or other fuel consumption. In addition, pesticides may contain nitroso compounds as impurities. (48 refs)

- 79-4828 N-Nitrosamines: Their Occurrence and Prevention. (Dut) Stephany, R. W. (Afdeling voor Biologisch-Residu Onderzoek, Rijksinstituut voor de Volksgezondheid, Bilthoven, Netherlands); Schuller, P. L. *Chem Weekbl*: 373-376; 1979.

Studies of N-nitrosamines (NA's) and their occurrence are reviewed. About 100/130 NA's investigated for their biological effects were found to be carcinogenic. These compounds are characterized by strong organotropicity. Symmetric dialkyl-NA's, administered po, induce liver cancer, but asymmetrical methylalkyl-NA's usually induce cancer of the esophagus. Some carcinogenic NA's also occur in food; they include N-nitrosodimethylamine, N-nitrosodiethylamine, N-nitrosopyrrolidine, and N-nitrosopiperidine. Dialkyl-NA's such as N-nitrosodimethylamine are found in meat and meat products, seafood, cheese, distilled beverages, wine, and beer. Cyclic NA's such as N-nitrosopyrrolidine are found in meat, seafood, and beer. Dialkyl-NA's and N-nitrosornicotine are found in tobacco smoke. (10 refs)

- 79-4829 Chromosomal Effects of Mutagenic Carcinogens and the Nature of the Lesions Leading to Sister Chromatid Exchange. (Eng) Wolff, S. (Lab. Radiobiology, Univ. California, San Francisco, CA 94143). In: *Mutagen-induced Chromosome Damage in Man. Proceedings of a Symposium held in Edinburgh, Scotland, July 7-8, 1977*. Medical Research Council (Edinburgh, Scotland): 355 pp.; 208-215; 1978.

Studies of the induction of sister chromatid exchanges

(SCE's) in Chinese hamster ovary (CHO) cells and xeroderma pigmentosum (XP) cells are reviewed. In CHO cells, UV rays and chemical mutagens such as acetox-yacetylaminofluorene and 4-nitroquinoline 1-oxide induce long-lived DNA lesions, which lead to SCE formation when the cells pass through S. When SCE's are formed, both strands of the DNA double helix exchange with those in the sister chromatid. After UV treatment, the long-lived lesions do not seem to be thymine dimers since the production of SCE's is independent of excision repair, as measured by unscheduled synthesis or repair replication. Treatment of repair-defective XP cells with alkylating agents has indicated that the lesions responsible for SCE formation might be a minor unexcisable fraction of the damage. One possible candidate for this would be alkylation at the O⁶ position of guanine, which is ordinarily a minor alkylation product. (34 refs)

- 79-4830 Smoking and Health: A Report of the Surgeon General. (Eng) U. S. Department of Health, Education, and Welfare (Office Assistant Secretary Health, Public Health Service, U.S. Dept. Health, Education, and Welfare, Washington, DC). (Washington: Dept. Health, Education, and Welfare): 1164 pp.; 1979.

This new surgeon General's Report on Smoking and Health is a compendium of new data confirming the conclusions of the original report published in 1964 and it reveals, with dramatic clarity, that cigarette smoking is even more dangerous than was supposed in 1964. It presents sobering information about women and smoking. Evidence suggests that mothers who smoke during pregnancy may create long-term, irreversible effects on their babies. The female mortality rate from lung cancer was three times higher in 1978 than in 1964, and women who have smoking characteristics similar to those of men experience similar overall mortality rates. Health risks to smokers exposed to certain occupational hazards are dramatically increased, and they include workers in the asbestos, rubber, coal, textile, uranium, and chemical industries. New evidence has accumulated with respect to relationships between tobacco use and cancer of the larynx, oral cavity, esophagus, urinary bladder, kidney, and pancreas. Cigarette smoking is causally related to lung cancer in men and women, and the risk of developing lung cancer increases with increasing dosages of smoking, as measured by number of cigarettes smoked per day, duration of smoking, age of initiation of smoking, degree of inhalation, tar and nicotine content of cigarettes smoked, and several other measurements. Prospective studies have shown that mortality rates from cancer of the oral cavity, larynx, pharynx, and esophagus are approx equal in users of cigars, pipes, and cigarettes. Although several factors appear to be involved in lip cancer development, pipe smoking alone or in combination with other forms of smoking is causally related to this cancer. Pipe and cigar tobacco condensates have a carcinogenic potential comparable to that of cigarette condensates. (3303 refs)

- 79-4831 α , β Mannitone, a New Industrial Material with Unknown Benefits and Risks. (Eng) Schneiderman, M. A. (Field Studies and Statistics Program, NCI, Bethesda, MD 20014). *IARC Sci Publ* (25): 237-239; 1979.

α , β -mannitone, a substance made from old automobile tires, has not been completely characterized, and its risks and benefits are discussed. The substance has been proposed for use as a gasoline substitute. (no refs)

- 79-4832 The Genotoxic Effects of 2,4,5-T. (Eng) Grant, W. F. (Genetics Lab., McGill Univ., Macdonald Campus, Ste. Anne de Bellevue, Quebec H9X 1CO, Canada). *Mutat Res* 65(2): 83-119; 1979.

The cytogenetic, carcinogenic, and teratogenic properties of the herbicide 2,4,5-trichlorophenoxyacetic acid (2,4,5-T) are reviewed. Commercial formulations contain up to 0.1 ppm of the contaminant dioxin (2,3,7,8-tetrachlorodibenzo-p-dioxin, TCDD), which causes birth defects and tumors in animals at levels <100 parts per thousand. 2,4,5-T is a clastogen that produces chromosome aberrations, including bridges and micronuclei, in a variety of animal and plant species. In addition, 2,4,5-T induces cell enlargement, lengthens the duration of the mitotic cycle, extends DNA synthesis, induces mitosis, and causes chromosome contraction, stickiness, and sticky bridges, all at low concentrations. C mitoses, multinucleate cells, polyploidy, reduced fertility, and species resistance have also been reported. In vivo production of chromosome aberrations in humans is inconclusive. The emulsifiers and solvents in commercial preparations of 2,4,5-T also induce chromosome aberrations. In >20 experiments involving 15 different systems, only 3 reported 2,4,5-T to be mutagenic: 2/4 sex-linked lethal tests in *Drosophila* and 1/2 studies with *Saccharomyces cerevisiae*. In one study in which 2,4,5-T was given to mice in daily doses of 21.5 mg/kg in the diet, the herbicide did not increase the number of tumors significantly. In another study, administration of 12 mg/kg/day in the diet significantly increased the incidence of neoplastic lesions in C3Hf mice. Although the data on teratogenicity are not clear-cut, several reports suggest that 2,4,5-T is teratogenic with and without TCDD and that 2,4,5-T and TCDD may potentiate teratogenicity. (131 refs)

- 79-4833 The Development of Various Formulations of Vulcanizing Accelerators. (Ger) Rijnders, R. F. (Akzo Chemie BV, Amersfoort, Netherlands); Katzanevas, A. *Gumm Asbest Kunststoffe* 32(5): 309, 312-316; 1979.

The hygienic, toxicological, technological, and economical aspects of vulcanizing accelerators in rubber production

are reviewed. Experiments on laboratory animals demonstrated the carcinogenic and teratogenic effects of certain vulcanizing accelerators (not specified). These findings prompted rubber manufacturers to undertake retrospective studies into the causes of death among their workers. The results obtained so far have not confirmed the teratogenic and bladder cancer-inducing effects of ethylene thiourea, a substance thought to be carcinogenic and teratogenic. (31 refs)

- 79-4834 Drug-Induced Second Diseases in Patients with Rheumatism. Possibilities of Prevention and Therapy. (Ger) Chlud, K. (II. Medizinische Abteilung, Kaiser-Franz-Joseph-Spital der Stadt Wien, Kundratstrasse 3, A-1100 Vienna, Austria). *Therapiewoche* 29(23): 3981-4004; 1979.

D-Penicillamine treatment causes reversible bone marrow aplasia and lupus erythematosus in some patients with rheumatism. A significantly increased incidence of neoplasms and systemic diseases was observed in rheumatic patients following long-term therapy with cytostatics, eg, triaziquone. (56 refs)

- 79-4835 Mutagenic Agents: Methods of Detection and Clinical-Pathological Correlations. (Ita) Migone, N. (Cattedra di Genetica medica, Universita, Parma, Italy); Savi, M. *Recent Prog Med* 65(4): 340-365; 1978.

The general problems of mutagenesis, mutagenic agents, and test systems for their detection are reviewed. Close correlations were found between the mutagenic and carcinogenic activities of various substances (aromatic amines, alkylating agents, polycyclic aromatic hydrocarbons, esters, epoxides, carbamates, nitroaromatic and heterocyclic compounds, nitrosamines, toxins, antibiotics, cigarette smoke condensate, azo dyes, and diazo compounds). Some potent mutagens (triaziquone, triethylenephosphoramide, triethylene melamine, butylnitrosocarbamide, and methylmethane sulfonate), and weak mutagens (tripaflavine, 3,4-benzopyrene, and aflatoxin) were found to have mutagenic activity both in mammals and in microorganisms without metabolic activation, while hydrazine and captan (potent mutagens), as well as caffeine, dichlorvos, formaldehyde, and urethane (weak mutagens), were found to be mutagenic in microorganisms but not in mammals. Cyclophosphamide, nitrosomorpholine, dimethylnitrosamine, and dinitrosopiperazine were found to be non-mutagenic in microorganisms and mammals alike. (87 refs)

- 79-4836 Current Status of Experimental Chemical Carcinogenesis and Its Applications to Human

Cancer Risk. (Eng) Lijinsky, W. (Chemical Carcinogenesis Program, Frederick Cancer Res. Center, Frederick, MD 21701). *Cancer Res* 39(7, part 2): 2887-2890; 1979.

Experimental chemical carcinogenesis and its application to human cancer risks are reviewed. Polynuclear hydrocarbons comprise the most extensively studied group of carcinogens. Their chemical structure specificity compatible with carcinogenicity is quite marked. The most notable feature of these carcinogens is their restricted carcinogenic action. At low doses, they can also act as initiating agents. A recent study indicated that phenobarbital acts as a promoting agent in the liver of rats treated with low doses of carcinogens. Ethanol may act by a similar mechanism as a tumor promoter for human liver. It is reasonable to assume that the cancers seen in humans are the result of the compounding of a large number of relatively small exposures to compounds that increase cancer risk. All main classes of carcinogens except the N-nitroso compounds show a strong species specificity. No species has been found to be resistant to nitrosamines, and it may be significant that many N-nitroso compounds are found in the environment. The most notable characteristic of these compounds is their pronounced organ specificity. Problems related to extrapolation from experimental animal carcinogenesis are also discussed. Such studies provide information on the patterns and mechanisms of action of carcinogens. (13 refs)

- 79-4837 Organics. (Eng) Chian, E. S. (Sch. Civil Engineering, Georgia Inst. Technology, Atlanta, GA); DeWalle, F. B.; Meng, H.; Norman, D. *J Water Pollut Control Fed* 51(6): 1134-1171; 1979.

The results of studies on the detection, identification, and quantification of a number of organic compounds are summarized and tabulated together with the methods used in these studies. Compounds considered include detergents and surfactants; aliphatic and aromatic hydrocarbons; pesticides, chlorinated hydrocarbons, and related compounds; humic acids and naturally occurring organics; and organics present in water. - 79-4838 Cell Regulation and Cancer. (Eng) Weinstein, I. B. (Columbia Univ. Coll. Physicians and Surgeons, New York, NY 10032). *Differentiation* 13(1): 65-66; 1979.

The characteristics of tumor-initiating and -promoting agents are presented, and the molecular nature of active derivatives of the tumor initiator benzo(a)pyrene is reviewed. In addition, the cellular effects of the most efficient tumor promoter, 12-O-tetradecanoylphorbol-13-acetate, are described. (11 refs)

REVIEW

- 79-4839 Aryl Hydrocarbon (Benzo(a)pyrene) Hydroxylase Induction in Cells in Culture. (Eng) Whitlock, J. P. (Dept., Pharmacology, Stanford Univ. Sch. Medicine, Stanford, CA 94305); Gelboin, H. V. *Pharmacol Ther [A]* 4(3): 587-599; 1979.

The aryl hydrocarbon hydroxylase (AHH) enzyme system is inducible in cultured cells by a wide variety of polycyclic hydrocarbons. The inducible cells include secondary cultures, cell lines, cell hybrids, and lymphocytes and monocytes. In general, the enzyme level rises after a 30-60 min lag period following the addition of inducer. The increase in AHH levels can reach thirtyfold or greater at 16 hr. The induction process is sensitive to actinomycin D and is, therefore, dependent on RNA synthesis. This dependence occurs only during the first few hours of the induction process. The induction process requires RNA synthesis initially, followed by protein synthesis, and these steps can be experimentally dissociated. The induction-specific RNA is not ribosomal RNA and is probably poly A-containing heterogeneous nuclear RNA. Induction can be accomplished by the addition of a polycyclic aromatic hydrocarbon inducer, by temporary inhibition of protein synthesis, or by cyclic AMP. These induction processes are synergistic, suggesting that there are at least three mechanisms of AHH induction. The gene action system responsible for AHH induction interacts in some manner with the steroid system regulating tyrosine aminotransferase, since synergistic effects between the steroid and polycyclic hydrocarbons are observed. Studies with cloned cells indicated that a nongenetic regulatory mechanism may influence basal and inducible AHH levels; studies with human-mouse hybrids indicate that AHH expression is associated with human chromosome 2. Studies of AHH induction in lymphocytes and monocytes of fraternal and identical twins suggest strong genetic determinants in AHH levels in humans. (47 refs)

- 79-4840 The *Ah* Locus: Genetic Regulation of the Metabolism of Carcinogens, Drugs, and Other Environmental Chemicals by Cytochrome P-450-mediated Monooxygenases. (Eng) Nebert, D. W. (Nat. Inst. Child Health and Human Development, NIH, Bethesda, MD); Jensen, N. M. *CRC Crit Rev Biochem* 6(4): 401-437; 1979.

The role of the *Ah* locus in genetic regulation of the metabolism of carcinogens and other compounds by cytochrome P-450-mediated monooxygenases (MO's) is reviewed. The *Ah* locus controls the induction of at least 20 MO activities and associated cytochrome(s) P₁-450 by 3-methylcholanthrene (3-MC) and other polycyclic aromatic compounds. N-Acetylarlyamine N-hydroxylase induction and the induction of some of the other 20 MO activities may be associated with other cytochromes. Other induced macromolecules that appear to be under the same regulatory control include microsomal uridine diphosphate glucuronosyltransferase, cytosolic reduced NAD(P):mena-

dione oxidoreductase, and cytosolic ornithine decarboxylase. One product of the regulatory *Ah* gene is believed to be a cytosolic receptor protein that has a high affinity for polycyclic aromatic inducers and appears to have diminished affinity in mice that are unresponsive to aromatic hydrocarbons. Regulation of responsiveness probably involves several alleles at more than one locus, but differences between responsive C57BL/6 and nonresponsive DBA/2 mice can be almost completely explained by differences at the *Ah* locus. Compared with *Ah-d/Ah-d* mice, *Ah-b/Ah-b* and *Ah-b/Ah-d* mice show, among other things, a high susceptibility to 3-MC- and benzo(a)pyrene (BP)-induced sc sarcomas, 3-MC-induced lung tumors, and BP-induced leukemia. The *Ah-b* allele is associated with a high mutational rate in *Salmonella* by metabolic activation of several chemical carcinogens and increases in numerous specific metabolites of chemical carcinogens bound to DNA nucleosides. There is also evidence that heritable variations in aryl hydrocarbon hydroxylase inducibility occur in humans. (169 refs)

- 79-4841 The Role of Glutathione and Glutathione S-Transferases in the Metabolism of Chemical Carcinogens and Other Electrophilic Agents. (Eng) Chasseaud, L. F. (Dept. Metabolism and Pharmacokinetics, Huntingdon Res. Centre, Huntingdon, England). *Adv Cancer Res* 29: 175-274; 1979.

The role of glutathione (GSH) and GSH S-transferases in the metabolism of chemical carcinogens and other electrophilic agents is reviewed. The mode of action, assay and stability, intracellular location, tissue distribution, species distribution, maturation, induction, inhibition, and sex differences of the GSH S-transferases are covered. Metals and 22 different classes of compounds (including mutagens and carcinogens) that conjugate with GSH are treated individually. Conjugation with nucleophilic GSH is important for the elimination of electrophilic foreign compounds from the body, and conjugation is generally catalyzed by the GSH S-transferases. GSH conjugates are most likely excreted in the bile, but the subsequent fate of the biliary-excreted products has not been fully investigated. Clues as to whether or not GSH is involved in conjugation with a particular electrophile can be provided by studies of the depletion of hepatic and, sometimes, extrahepatic GSH that may occur when the electrophile or its precursors are administered to laboratory animals. None of the studies reviewed clearly showed that GSH and its associated S-transferases prevented a potential carcinogen from exerting its effects. There is, however, an apparent inverse correlation between the level of ligandin-binding activity in the liver cell, which is affected by certain drug or hormonal manipulations, and the susceptibility of the cell to chemically induced carcinogenesis. (698 refs)

- 79-4842 The Pharmacology of Graft Rejection. (Eng) Lewis, G. P. (Dept. Pharmacology, Royal

Coll. Surgeons England, London WC2A 3PN, England); Mangham, B. A. *Trends Pharmacol Sci* 1(Inaug. Issue): 18-21; 1979.

Graft rejection (GR) is a complicated process in which more than one mediator participates. Pharmacological studies of GR, which are reviewed here, have been aimed at identifying these mediators. Specific topics include the role of histamine and prostaglandins in GR, interaction of mediators with cyclic AMP and cyclic guanosine monophosphate, and the possible role of complement in GR. (18 refs)

- 79-4843 Enzymic Modification of Environmental Intoxicants: The Role of Cytochrome P-450. (Eng) Blumberg, W. E. (No affiliation given). *Q Rev Biophys* 11(4): 481-542; 1978.

The distribution of environmental intoxicants on the earth and the metabolism of these chemicals by in vivo detoxification systems are reviewed. Many intoxicants are detoxified by cytochrome P-450 enzyme systems, and others are potentiated by the same systems. The intoxicants that are potentiated by cytochrome P-450 are generally believed to be more dangerous than those that are detoxified by it. (57 refs)

- 79-4844 The Antioxidant Vitamins. (Eng) Johnson, F. C. (J.A. Pye Res. Centre, Haughley Res. Farms, Ltd., Haughley Stowmarket, England). *CRC Crit Rev Food Sci Nutr* 11(3): 217-309; 1979.

The chemistry and analysis of vitamin C and vitamin E are reviewed, as are their sources and fates during processing and cooking, their absorption and metabolic actions in vivo, and their participation in metabolic defense mechanisms. The increasing importance of work on free-radical reactions, their toxicity and carcinogenic action, and their relation to the metabolism of metals, particularly Fe, Cu, Se, and Zn, shows a number of metabolic pathways with which both vitamins interact. (505 refs)

- 79-4845 Bronchial Epithelium and Cigarette Smoking (5 Letters to Editor). (Eng) Kurt, T. L. (Southwestern Medical Sch., Dallas, TX 75205); Haack, D. G.; Miller, G. H.; Harada, W.; Pearson, L.; Schumaker, J. A.; Bernfeld, P.; Auerbach, O.; Hammond, E. C.; Garfinkel, L. *N Engl J Med* 300(24): 1394-1396; 1979.

A report that fewer precancerous changes occurred in the lungs of male smokers who died during 1970-1977 than in those who died during 1955-1960, presumably due to the lower consumption of tar and nicotine, is commented on.

It is necessary to assess lifelong exposure to tar and nicotine rather than to classify a person as a smoker or nonsmoker. The earlier set of bronchial epithelium sections showed serious denudation, which would probably bias the evaluation of histologic changes. The age distribution was different in the two groups. The newer cigarettes burn for much shorter periods, and thus the two groups cannot be compared accurately based on number of cigarettes smoked/day. The authors of the report respond to these comments. (19 refs)

- 79-4846 Urinary Bladder Cancer: Potentials of and Problems Associated with Early Intervention Strategies. (Eng) Bryan, G. T. (Div. Clinical Oncology, Dept. Human Oncology, Clinical Science Center, 600 Highland Ave., Madison, WI 53792). *Semin Oncol* 6(2): 161-165; 1979.

Early intervention strategies in bladder cancer (BC) are reviewed. Because a disease state can be divided pathogenetically into identifiable stages, attempts to alter the course of the disease by modifying one of these stages are attractive intervention strategies. To form a clinically detectable neoplasm (approx 1 cm³, 10⁹ cells), a neoplastic cell and its progeny must undergo about 30 cell divisions; only about 7 more divisions are required to form a lethal mass. Hence, prevention and intervention strategies must occur before a detectable tumor exists. Since the average age at diagnosis of BL is 68 yr in the US, it is imperative to identify prospectively those individuals at increased risk. Recognized risk factors include age, sex, occupation, and smoking habits; possible risk factors are prior pelvic irradiation and consumption of coffee or artificial sweeteners. One intervention strategy is to add an agent or agents to the environment of an individual to interfere with hypothetical bladder carcinogenic mechanisms. These additives have one of three modes of action: (1) interference with carcinogen-target interaction (eg, β -glucuronidase inhibition, free-radical scavenger agents), (2) alteration of the molecular balance between activation and detoxication toward detoxication (eg, detoxication enzyme induction, inhibition of activation enzymes, addition of cofactors to inhibit carcinogen or promoter formation), and (3) inhibition of the growth and development of initiated cells by retinoids, protease inhibitors, etc. The effectiveness of these methods to date, largely unspectacular, is summarized. (28 refs)

- 79-4847 Anabolic Steroids and Liver Tumors. (Ger) Scheuer, A. (Medizinische Klinik, Universität Marburg, Mannkopfstr. 1, 3550 Marburg, W. Germany); Gerdes, H.; Lehmann, F. G. *Dtsch Med Wochenschr* 104(21): 779-783; 1979.

Thirty-two cases of liver tumors following treatment with

anabolic steroids are reviewed and available data summarized. The drugs used were oxymetholone, methyltestosterone, methandienone, stanozolol, fluoxymesterone, oxandrolone, norethandrolone, nandrolone decanoate, testosterone propionate, testosterone enanthate, and testosterone cyclopentyl propionate. Eighteen patients received monotherapy, 13 sequential therapy. The duration of the treatment was 0-12 mo in 5 cases, 13-60 mo in 8, 61-120 mo in 12, and over 120 mo in 1. The total dose was 0-50 g in 6 cases, 51-100 g in 7, 101-150 g in 2, and over 150 g in 9. Five patients were aged 0-10 yr, 10 11-20 yr, 9 21-30 yr, and 8 were aged over 30 yr. The histological diagnosis was hepatocellular carcinoma in 14 cases, well-differentiated hepatoma in 9, hepatocellular adenoma in 8 (associated with the hepatocellular carcinoma in 1 case), and focal nodal hyperplasia in 2; peliosis hepatis was seen additionally in 11 cases. (58 refs)

- 79-4848 Cardiac Glycosides and Breast Cancer (Letter to Editor). (Eng) LeWinn, E. B. (8801 Stenton Ave., Philadelphia, PA 19118). *Lancet* 1(8127): 1196-1197; 1979.

Comments are made on the findings that patients on cardiac glycosides (digoxin) had breast cancers (BC) with a tumor cell population composed of cells that are smaller and more uniform in morphology, density, and size than those in patients not on digitalis (DT) and that after 2 yr of BC, distant spread was less common in patients on digitalis treatment. There have been several reports of a connection between the estrogen-like structure of DT and its ability to cause gynecomastia in men and in postmenopausal women. Cardiac glycosides might interfere with estrogen receptors, as suggested, but in some cases they also might have an exacerbating effect on BC. (5 refs)

- 79-4849 Is the Hypothesis on the Role of Rauwolfia Preparations in the Development of Breast Cancer Substantiated? (Rus) Tikhonova, H. A. (Cancer Res. Center, Moscow, USSR); Lazarev, N. I.; Samoilenko, L. A. *Klin Med (Mosk)* 57(5): 52-56; 1979.

Controversial data on the role of rauwolfia alkaloids, primarily reserpine, in the etiology of breast cancer are reviewed. In a number of experiments, reserpine was found to stimulate prolactin secretion, which causes cancer of the mammary gland in Sprague-Dawley rats. However, other data indicate that prolactin stimulates the function of mammary gland cells and not their division, and an elevated prolactin level can prevent or even inhibit the growth of mammary gland tumors. A retrospective analysis of the case histories of 494 women with primary breast cancer and 478 women with cancer at other sites (97 pulmonary carcinomas, 230 stomach carcinomas, 151 cervical carcinomas) showed that concomitant hypertension

was present in 118/494 and 91/478 patients, respectively. Of 118 patients with breast cancer and hypertension, 39 had received rauwolfia drugs, compared with 41/91 patients with other cancers and hypertension. The absence of a significant difference in the number of patients receiving rauwolfia drugs indicates that they do not have a carcinogenic effect. (19 refs)

- 79-4850 A Unifying Concept of Chorionic Gonadotrophin Production in Malignancy. (Eng) Skrabanek, P. (Dept. Endocrinology, Mater Misericordiae Hosp., Dublin, Ireland); Kirrane, J.; Powell, D. *Invest Cell Pathol* 2(2): 75-85; 1979.

The production of human chorionic gonadotropin (HCG) during malignancy is reviewed. HCG production by germ cell tumors is related to the presence of chorionic tissue or syncytial giant cells in which the presence of HCG can be demonstrated by immunocytochemistry. HCG-producing tumors other than gestational choriocarcinoma or germinomatous tumors are quite rare and are limited to the lung, liver, gastrointestinal tract, adrenal cortex, and urogenital tract. The histology and distribution of these "somatic" HCG-producing tumors are characteristic for the individual organs. The somatic and germ cell tumors associated with excess HCG production show marked similarity in clinical behavior, histology, and endocrine profile. This may indicate a common embryological origin or a common biochemical and genetic organization of certain malignant somatic and germ cells. Elevated HCG levels are also found in patients with various nonmalignant conditions. (127 refs)

- 79-4851 Indications, Modalities and Limits of Estrogen Therapy (Other than Contraception). (Fre) de Lignieres, B. (Service d'endocrinologie et de gynécologie medicale, Hopital Necker, 149, rue de Sevres, 75730 Paris Cedex 15, France); Mauvais-Jarvis, P. *Rev Prat* 29(21): 1723-1726, 1729-1732; 1979.

The physiological effects and long-term side effects of estrogen therapy in menopause are reviewed. The risk of cancer of the breast and endometrium is linked with the possible accumulation of estrogen in the target tissues and with the development of a zone of hyperplasia in the galactophores and endometrium. The risk of carcinogenesis can be prevented by the intermittent use of estrogens (during 3 wk/mo) and by the systematic administration of a synthetic progestogen for at least 10 days/mo. (11 refs)

- 79-4852 Oestrogen Therapy and Endometrial Cancer (Letter to Editor). (Eng) McDonald, A. D. (Dept. Epidemiology, St. Mary's Hosp. Medical Sch.,

London W2 1PG, England). *Lancet* 1(8129): 1288-1289; 1979.

Contrary to a previous editorial, an association between estrogen therapy (ET) and endometrial cancer (EC) has not yet been established. Since menopausal women on (ET) are subject to vaginal bleeding, silent EC's are likely to be detected and, since the distinction between hyperplasia and cancer is far from clear, some borderline cases may be classified as cancer. If EC patients are compared with nonbleeding controls (which was the case in 7 studies cited in the editorial), a spurious association with ET will be found. The editor agrees that presymptomatic EC may be more readily detected in women taking estrogens. Case selection should be restricted to women with invasive cancer, in whom there is little doubt about the diagnosis. Then, a positive association will still be evident. (12 refs)

- 79-4853 The Prostatic Carcinoma in Laboratory Animals. A Bibliographic Survey from 1900 to 1977. (Eng) Rivenson, A. (Naylor Dana Inst. Disease Prevention, American Health Foundation, Dana Road, Valhalla, NY 10595); Silverman, J. *Invest Urol* 16(6): 468-472; 1979.

The spontaneous and artificially-induced occurrence of prostatic carcinoma in laboratory animals is reviewed. Contrary to the frequent occurrence of prostatic adenocarcinoma in man, laboratory animals have a low incidence of clinically manifest carcinoma of the prostate. The development of human prostatic cancers grafted into nude mice appears to be neither hormone nor sex-dependent. Almost all major carcinogens produce tumors of the prostate in laboratory animals. X-irradiation, steroid hormones, and various chemical carcinogens have been successfully employed, and malignant prostatic tissue has been obtained by inoculating normal hamster prostate with simian virus 40. A combination of hormones and carcinogens appears to be most satisfactory for the production of experimental animal models for human prostatic adenocarcinoma. (70 refs)

- 79-4854 Significance of the Working Environment for the Lungs. (Ger) Konetzke, G. (Abt. Berufs-krankheiten, Zentralinstitut für Arbeitsmedizin der DDR, Noldnerstrasse 42-44, DDR-1134 Berlin, E. Germany). *Z Gesamte Inn Med* 34(6): 57-59; 1979.

Occupational diseases of the lungs account for about 10% of all occupational diseases in E. Germany, averaging about 1,200 cases/yr. The incidence is highest for silicosis and asbestosis (about 300 cases/yr), which predispose to lung carcinoma and malignant mesothelioma. (13 refs)

- 79-4855 Endocrine Effects of Testicular Neoplasms. (Eng) Fox, H. (Dept. Pathology, Univ. Man-

chester, Manchester, England); Reeve, N. L. *Invest Cell Pathol* 2(2): 63-73; 1979.

Hormone abnormalities occurring in patients with testicular tumors are reviewed. Abnormalities of sex steroid secretion occur much more commonly than is generally realized. Gynecomastia in men with choriocarcinoma appears to result from an elevation of combinations of hormones with a physiological relationship to each other, and hormone disturbances in men with testicular seminomas or teratomas appears to be due to the presence of undetected choriocarcinomatous foci. Very few true sertoli cell tumors seem to be associated with signs of hormone disturbance. In one patient with a granulosa cell tumor, a low excretion of 17-oxosteroids and follicle-stimulating hormone and a marked elevation of urinary estrogens were demonstrated, abnormalities that lend support to the presumed estrogenic capacity of these rare neoplasms. Interstitial cell tumors appear to secrete estrogens and a variety of weak androgens. Some interstitial cell tumors have features typical of adrenocortical tissue. Gonadoblastomas also appear to be hormonally active, this activity being independent of their Leydig cell content. Other endocrine abnormalities associated with testicular tumors are quite rare. They include Cushing's syndrome, hypercalcemia, hyperthyroidism and the carcinoid syndrome. (94 refs)

- 79-4856 The Relevance of Photobiology. (Eng) Giese, A. C. (Dept. Biological Sciences, Stanford Univ., Stanford, CA 94305). *Bioscience* 29(6): 353-357; 1979.

In this survey of the contribution of photobiology to biology, attention is focused on research opportunities, especially those at the molecular level. If visible light is absorbed by critical molecules, it can be as effective as UV light in producing photobiological effects, such as activation of some enzymes, retardation of cell growth in culture, induction of chromosome aberrations and slowing of DNA synthesis in tissue culture cells, mutagenesis, and killing of repair-deficient bacteria. (24 refs)

- 79-4857 Plutonium and Other Heavy Radioactive Elements in Nature. (Ger) Keller, C. (Schule für Kerntechnik, Kernforschungszentrum Karlsruhe GmbH, Postfach 3640, D-7500 Karlsruhe 1, W. Germany); de Alleluia, I. B. *Chemiker-Zeitung* 103(4): 139-153; 1979.

The occurrence, origin, and general ecological significance of plutonium and other heavy radioactive elements in nature are reviewed. Due to very low uptake of plutonium by biological systems (resuspension and migration in soil and plants), the plutonium load of man is very low, averaging 5 p(pico)Ci/person in the U.S. The accumulation of

^{210}Po in tobacco plants represents a real hazard for smokers because it is volatile even below the combustion temperature of the cigarette (750 C) and is inhaled. The inhaled radioactivity is estimated at 0.1 pCi ^{210}Po /cigarette, which may represent an additional radiation load of up to 36 rem (roentgen-equivalent-man) after long-term heavy smoking. This radioactivity can also have a cocarcinogenic effect with the polycyclic aromatic hydrocarbons inhaled in cigarette smoke. Uranium, added to the ceramic material from which dental prosthesis is prepared (permissible level 0.05 wt % in the U.S.), can cause an annual radiation dose of up to 130 rem in the buccal mucosa. (91 refs)

- 79-4858 Comments on "Leukemia Risk from Neutrons" (Letter to Editor). (Eng) Beebe, G. W. (Clinical Epidemiology Branch, NCI-NIH, Landow Bldg., Rm. 5A21, Bethesda, MD 20014); Land, C. E. *Health Phys* 36(3): 465-466; 1979.

Questions concerning a previous study on leukemia risk from neutrons are raised. It was suggested previously that 1 rad delivered to the active bone marrow by fast neutrons may confer a lifetime risk of about 800 leukemias per million persons, and that a 50-yr occupational exposure at the maximum permissible dose of 5 roentgen-equivalents-man/yr may lead to a life-time induction of 2% for leukemia and 10% for all fatal cancers. (5 refs)

- 79-4859 RBE for Carcinogenesis by Fission Neutrons (2 Letters to Editor). (Eng) Mole, R. H. (Medical Res. Council, Radiobiology Unit, Harwell, Didcot., Oxon. OX11 0RD, England); Rossi, H. H.; Mays, C. W. *Health Phys* 36(3): 463-465; 1979.

A previous paper seems to assume that the relative biological effectiveness (RBE) for cancer induction by fission neutrons, as compared with γ -rays, is the same for all tissues. However, there is already good evidence that fission neutrons are not necessarily much more effective carcinogenic agents in humans than are γ -rays. The authors of the paper reply that the extension of their analysis of leukemia risk to other cancers was tentative and does not exclude the possibility that the RBE for certain cancers might be less or, perhaps, more. Organs (ie, breast and thyroid) in which there seems to be a lower RBE are subject to strong endocrine control, and the apparent difference in RBE may be due to a complex interaction of various cell systems. (12 refs)

- 79-4860 The Burn Patient: II. Later Care and Complications of Thermal Injury. (Eng) Pruitt, B. A. (No affiliation given). *Curr Probl Surg* 16(5): 1-95; 1979.

The use of primary grafting for closure of full-thickness burns has reduced the occurrence of burn scar carcinoma. The av latent periods of scar tissue carcinoma in two series were 34 and 36 yr. Keratoacanthomas may represent an intermediate stage of disordered healing between that characteristic of hypertrophic scar and scar carcinoma. Chronic trauma and repetitive reepithelization of poorly vascularized burn scars are important in the etiology of scar malignancies, which are usually of squamous cell histology. (228 refs)

- 79-4861 Photochemotherapy and Risk of Skin Cancer (Letter to Editor). (Eng) Pembroke, A. C. (Dept. Dermatology, King's Coll. Hosp., London SE5 9RS, England); Hehir, M. E.; du Vivier, A. W.; Marten, R. H. *Lancet* 1(8129): 1299; 1979.

A prospective study of the risk of cutaneous carcinoma in psoriatic patients treated with po methoxsalen photochemotherapy (PCT) is discussed. The study indicated that patients treated with PCT were more prone to cutaneous carcinoma. However, this phenomenon could have been a result of previous treatment, such as ionizing radiation or arsenic. In addition, premalignant skin conditions (eg, solar keratoses or Bowen's disease) may have been present in the patients who developed epitheliomas after PCT. These conditions are difficult to diagnose in patients with severe psoriasis, and they might become obvious as the psoriasis clears upon PCT. (3 refs)

- 79-4862 Identifying and Treating Skin Malignancies. (Eng) Jessen, R. T. (Div. Dermatology, Univ. New Mexico Sch. Medicine, 2701 Frontier, NE, Albuquerque, NM 87131); Merwin, C. F. *Geriatrics* 34(6): 71-78; 1979.

The clinical presentation and treatment of skin malignancies are reviewed. Actinic keratoses are precancerous lesions that occur almost exclusively in fair-complexioned persons. Squamous cell carcinomas are found predominantly on sun-exposed areas; those arising in sun-damaged skin rarely metastasize, but those developing in sites of previous injury of chronic inflammation tend to metastasize. Bowen's disease is a squamous cell carcinoma that has not broken through the basement membrane into the dermis. The incidence of internal malignancies may be increased in Bowen's disease patients with lesions on non-sun-exposed areas of the body. Basal cell carcinomas are the most common skin cancers. They are locally invasive and rarely metastasize. Keratoacanthoma is a rapidly growing but usually self-involuting tumor. Malignant melanomas arise at the epidermal-dermal junction. Lentigo malignant melanomas have the best prognosis and nodular melanomas the poorest prognosis, especially tumors on the trunk. (21 refs)

- 79-4863 Relative Carcinogenic Effects of Different Mammography Techniques. (Eng) Muntz, E. P. (Dept. Radiology, Univ. Southern California, Los Angeles, CA 90033). *Med Phys* 6(3): 205-210; 1979.

Using recent data from the literature, a study was made of the significance of various assumptions concerning the appropriate measures for carcinogenesis in mammography and the shape of the dose-effects relationship. There is no way in principle to be "conservative" in a relative sense by assuming a given dose-response curve for the comparison of mammography techniques using different beam qualities. However, for nonextreme amounts of nonlinearity, there is typically no more than about a 20% max uncertainty for the entire mammography energy range. The uncertainties associated with the precise shape of the dose-effects relationship for carcinogenesis at low doses as well as the distribution of sensitive tissue in the breast make it difficult to select a best measure for the relative carcinogenic effects of different mammography techniques. The assumption of a linear dose-effects relationship favors the soft beam techniques, in comparison with dose-effects relationships with concave upward nonlinearities. The assumption of no "adipose shield" favors the hard beam techniques. The av dose per unit of entrance dose, which is directly proportional to the av carcinogenic effect for a linear effects relationship, can be determined for any breast thickness and composition. It is emphasized that although there is considerable uncertainty in specifying a reliable indicator of relative carcinogenic effects, the absolute risk can, with high probability, be conservatively estimated from a linear effect vs dose relationship used with an av dose. (10 refs)

- 79-4864 Urinary Bladder Carcinogenesis: Initiation-Promotion. (Eng) Cohen, S. M. (Dept. Pathology, St. Vincent Hosp., 25 Winthrop St., Worcester, MA 01604). *Semin Oncol* 6(2): 157-160; 1979.

A review of urinary bladder carcinogenesis in humans and animals is presented. A chemical etiology for bladder cancer (BC) was first suggested in 1895 in relation to aniline dyes. Since then, 2-naphthylamine, benzidine, 4-aminobiphenyl, N-2-acetylaminofluorene (AAF), N-butyl-N-(4-hydroxybutyl) nitrosamine (BBN), N-[4-(5-nitro-2-furyl)-2-thiazolyl]formamide (FANFT), and N-methyl-N-nitrosourea (MNU) have been implicated. Studies of AAF revealed the necessity of activating carcinogens to reactive electrophilic intermediates capable of reacting with nucleic acids or proteins. BBN and FANFT are bladder-specific carcinogens in animals. Animal models are useful because the pathology and course of BC in animals are similar to those in humans: simple hyperplasia progressing to nodular and papillary hyperplasia, to benign-appearing tumors, and then to noninvasive and, finally, invasive carcinomas, sometimes with distant metastases. Humans are likely to be exposed to low doses

of several chemicals at once, and these may have an additive or synergistic effect. Some substances are not complete carcinogens but possess either initiator or promoter properties. Initiation is rapid, irreversible, and likely to be a somatic mutation, but promotion is slower, initially reversible, and is likely due to the phenotype expression of initiated cells. Initiation-promotion in BC has been shown for MNU-sodium saccharin, MNU-sodium cyclamate, FANFT-sodium saccharin, FANFT-DL-tryptophan, 4-aminobiphenyl-DL-tryptophan, 2-naphthylamine-DL-tryptophan, and FANFT-L-tryptophan. Substances in rat urine appear to be capable of promoting BC in heterotopic rat bladders. (22 refs)

- 79-4865 Radiation Hazards and Control in Nigeria. (Eng) Bandele, S. D. (Dept. Radiology, Ahmadu Bello Univ. Hosp., Zaria, Nigeria). *Radiography* 45(533): 97-99; 1979.

The health hazards of ionizing radiation in Nigerian hospitals, where there is no organized control of its use, are discussed. Direct effects include erythema, hair loss, and sterility. Ionization may also cause changes in the configuration of the affected cells, possibly leading to cancer. The ways in which ionizing radiation-induced mutation may represent a serious hazard to future generations are described. (no refs)

- 79-4866 Biology of Cancer. (Fre) Dulbecco, R. (Salk Inst., La Jolla, CA). *Recherche* 10(100): 434-442; 1979.

The general biological aspects and mechanisms of cancer are reviewed. Recent studies have demonstrated that the transformation of a normal cell into a tumor cell is due to a specific gene of a virus integrated in the chromosomes of the infected cell. This gene is believed to induce the synthesis of a particular enzyme, which plays a primary role in tumor cell growth. An identical mechanism can also be used to explain chemical and physical carcinogenesis. (8 refs)

- 79-4867 Discussion Summary. (Eng) Wilkie, N. M. (Medical Res. Council Virology Unit, Inst. Virology, Glasgow, Scotland). *IARC Sci Publ* 24(1): 149-153; 1978.

A discussion of papers presented at a session of a symposium on herpesviruses (HV's) is summarized. Topics covered include the general sequence arrangement in the genomes of several HV's, analysis of defective herpes simplex virus type 1 (HSV-1) genomes, DNA replication, marker rescue experiments and the mapping of crossover points in intertypic recombinants between HSV-1 and

HSV-2, plasmid forms of Epstein-Barr virus DNA. (no refs)

- 79-4868 Discussion Summary. (Eng) Becker, Y. (Lab. Molecular Virology, Hebrew Univ., Hadassah Medical Sch., Jerusalem, Israel). *IARC Sci Publ* 24(1): 423-427; 1978.

Papers presented at a symposium on herpesviruses (HV's) provided information on some of the molecular events occurring during the replication of three HV's [herpes simplex virus (HSV), cytomegalovirus, and Epstein-Barr virus] in permissive and nonpermissive cells. The data covered analysis of the viral genome, molecular events in lytically infected cells (transcription and translation of viral messenger RNA, control of viral DNA replication, recombination of HSV DNA), and semipermissive interactions of HV's with cells. (no refs)

- 79-4869 The Structural Proteins and Glycoproteins of Herpesviruses: A Review. (Eng) Spear, P. G. (Univ. Chicago, Chicago, IL); Sarmiento, M.; Manservigi, R. *IARC Sci Publ* 24(1): 157-167; 1978.

Available information concerning the role of herpesvirus-specified structural proteins and glycoproteins in the morphogenesis and function of the virion is reviewed. The virions of different herpesviruses are similar with respect to the number and kinds of constituent polypeptides, in spite of variability in the structures of the individual polypeptides. The total number of virion polypeptides and glycopeptides ranges from 20 to 30 for different viruses. In general, no more than one-fourth of these polypeptides are detectable in naked nucleocapsids, suggesting that most of the virion polypeptides are acquired during the process of envelopment. Although the functions of most individual structural proteins have not been identified, the nucleocapsid proteins appear to serve primarily structural roles or may mediate packaging of the viral genome. The nonglycosylated envelope proteins appear to play essential roles in the process of envelopment, and the glycoproteins, which are probably all exposed to the virion surface, appear to mediate adsorption to and penetration of the host cell. Two of the herpes simplex virus glycoproteins have been identified as targets of neutralizing antibodies and one of these proteins has been shown to mediate viral penetration, probably by promoting fusion between the virion envelope and cell surface membrane. (43 refs)

- 79-4870 Transformation of Non-lymphoid Cells by Herpesviruses: A Review. (Eng) Rapp, F. (Dept. Microbiology, Milton S. Hershey Medical Center, Pennsylvania State Univ. Coll. Medicine, Hershey, PA); Shillito, E. J. *IARC Sci Publ* 24(1): 431-450; 1978.

Cell types that become transformed following herpesvirus infection and their relationship to malignant disease are reviewed. Most mammalian cells can be transformed by herpes simplex virus (HSV), which is usually partially inactivated. Temperature-sensitive mutants of HSV can transform cells without prior inactivation. The transformed cells may show a fibroblastoid or epithelioid morphology. Oncogenic cells of the former type induce tumors resembling fibrosarcomas and oncogenic cells of the latter type give rise to tumors resembling adenocarcinomas. Cells transformed by HSV do not release virus particles but they do synthesize virus proteins. Immunization of hamsters with cells transformed by HSV do not, however, protect against tumor isografts. Human cytomegalovirus (CMV), which is widespread throughout the population, can transform human cells. Guinea pig herpeslike virus (GPHLV) induces morphological transformation in guinea pig WBC and nonlymphoid cells. After 37 passages in vitro, the transformed cells are able to induce metastasizing fibrosarcomas in hamsters. Epstein-Barr virus (EBV) has been shown to infect only human B lymphocytes, but EBV DNA has been found in epithelial cells derived from nasopharyngeal carcinomas. The EBV genome can be maintained and expressed in transformed hybrid cells with a nonlymphoid morphology. Lucke herpesvirus has been found in frog renal tumors, but since other viruses have also been isolated from the tumor extracts, there is no proof that this virus causes cell transformation and tumors. (76 refs)

- 79-4871 Discussion Summary. (Eng) Schaffer, P. A. (Sidney Farber Cancer Inst., Harvard Medical Sch., Boston, MA). *IARC Sci Publ* 24(1): 577-580; 1978.

A discussion of papers presented at a session of a symposium on herpesviruses (HV's) is summarized. In a review of the transformation of nonlymphoid cells by HV's, the unavailability for study of human cell lines transformed by HV's and the fact that transplantation rejection antigens have not yet been identified in HV systems were stressed. The second major topic of the session concerned transformation of lymphoid cells by HV's and a comprehensive compendium of the characteristics of lymphoblastoid cell lines transformed by Epstein-Barr virus and other primate HV's. (no refs)

- 79-4872 Discussion Summary. (Eng) Pope, J. H. (Queensland Inst. Medical Res., Brisbane, Queensland, Australia). *IARC Sci Publ* 24(1): 655-656; 1978.

Papers presented at a symposium on herpesviruses (HV's) gave further evidence that a variety of HV's transform a variety of cells. The transformation should be regarded as being quite complex, and it may involve interactions bet-

ween several viruses, including possible endogenous C-type viruses. Changes in the biological properties of cytomegalovirus(CMV)-transformed cells, the effect of the physiological condition of the cells in CMV infection, and hazards that Epstein-Barr virus-infected cells may have to face before they become fully transformed were among the several other topics covered. (no refs)

- 79-4873 Comparison of Immune Responses and Viral Markers in Herpesvirus-associated Carcinomas: A Review. (Eng) Henle, W. (Div. Virology, Joseph Stokes, Jr. Res. Inst., Children's Hosp., Philadelphia, PA); Henle, G. *IARC Sci Publ* 24(II): 801-813; 1978.

The relationship of the following herpesviruses to their associated carcinomas is reviewed: Lucke tumor herpesvirus (LTHV), herpes simplex virus types 1 and 2 (HSV-1 and HSV-2), and Epstein-Barr virus (EBV). LTHV antigens have been detected in cultures of renal adenocarcinomas of the frog. EBV DNA or antigens have been detected in biopsy specimens of human nasopharyngeal carcinomas (NPC). Similar relationships have not been demonstrated between HSV-1 or HSV-2 and cervical or other squamous cell carcinomas. Carcinomas have been induced in frog embryos with LTHV, and there are unconfirmed reports of uterine carcinoma induction in mice by HSV-2. Transformation of normal epithelioid cells has been attained with HSV-1 and HSV-2, possibly with LTHV, but not with EBV. Virus-specific serology has revealed distinct patterns and titers of antibodies to EBV-related antigens in NPC patients, and the findings correlate with the stage and prognosis of the disease. Suggestive serologic results have also been obtained with HSV-1 and HSV-2. The data indicate an etiological role of LTHV in the Lucke tumor and a causal or at least contributory role of EBV in NPC. The evidence for a relationship between HSV-2 and cervical carcinoma and between HSV-1 and squamous cell carcinomas of the head and neck is tenuous. (37 refs)

- 79-4874 Discussion Summary. (Eng) Evans, A. S. (Yale Univ., New Haven, CT). *IARC Sci Publ* 24(II): 795-797; 1978.

At a discussion held after a session of a symposium on herpesviruses (HV's), the levels at which different immune systems affect the spectrum of HV infections were reviewed. T cells appear to be the major cells involved in the control of primary and recurrent infections. Latent HV infections were defined and classified, the cells in which different HV's are latent identified, and the use of temperature-sensitive mutants in studying the biochemistry of the process described. Cell-mediated immunity to HV's develops in both natural and experimental infections;

cellular immunity is involved in the control of these primary infections. (no refs)

- 79-4875 Discussion Summary. (Eng) Munk, K. (Institut für Virusforschung, Deutsches Krebsforschungszentrum, Heidelberg, W. Germany). *IARC Sci Publ* 24(II): 927-929; 1978.

A discussion of papers presented at one session of a symposium on herpesviruses (HV's) is reviewed. Papers on different host/HV systems, such as infections of fish, frogs, birds, and mammals (including humans), on the correlation between serological data and the clinical course of malignancies of possible HV etiology, and on viral markers in HV-associated lymphomas and host defenses against the oncogenic effects of lymphotropic HV were among the many covered. (no refs)

- 79-4876 Discussion Summary. (Eng) Frenkel, N. (Univ. Chicago, Chicago, IL). *IARC Sci Publ* 24(I): 261-265; 1978.

Studies presented at one session of a symposium on herpesviruses (HV's) concerned HV-specific antigens, and the findings are summarized under four headings: antigenic relatedness of HV's, purification of individual viral antigens, tumor-associated viral antigens, and functional studies of virus-specified polypeptides. (no refs)

- 79-4877 The Immunology of Primary and Recurrent Herpesvirus Infection: An Overview. (Eng) Nahmias, A. J. (Div. Infectious Diseases and Immunology, Dept. Pediatrics, Emory Univ. Sch. Medicine, Atlanta, GA); Ashman, R. B. *IARC Sci Publ* 24(II): 659-673; 1978.

The immunology of primary and recurrent herpesvirus infection is reviewed. It appears that many herpesviruses can be present in circulating leukocytes in a latent or infectious form. Herpetic infection induces numerous changes in the cell membrane, and the various antigens of the virus or virus-infected cells stimulate a multitude of humoral and cell-mediated responses. The latter may differ according to virus strain and may show cross-reactivity among different strains. Several common patterns in the immune responses to primary infection have been found. Antibodies of the Ig-M class are usually detected within 1-3 wk after infection and are usually of short duration. The persistence of IgG antibodies will depend on their reactivity to particular herpesvirus antigens: neutralizing antibodies generally persist longer than complement-fixing antibodies. IgE antibodies to herpes simplex viruses have been detected within 1 wk after infection in rabbits. Endogenous or exogenous recurrences may help maintain antibody levels. It is not

REVIEW

possible at present to pinpoint which of the various effector systems is the crucial one in determining the outcome of a primary infection. (65 refs)

- 79-4878 Persistent, Chronic, and Latent Infections by Herpesviruses: A Review. (Eng) Stevens, J. G. (Reed Neurological Res. Center, Dept. Microbiology and Immunology, Univ. California, Sch. Medicine, Los Angeles, CA). *IARC Sci Publ* 24(II): 675-685; 1978.

Persistent, chronic, and latent infections by herpes simplex virus (HSV), Epstein-Barr virus (EBV), and the Lucke agent (LV) are reviewed. HSV appears to establish latent infections which are selectively maintained in neurons. The form in which the viral genome persists in these cells and how the infection is maintained over time is not understood. Latent EBV is maintained in neoplastic B-lymphocytes and probably in normal and malignant epithelial cells of the nasopharynx as circular extrachromosomal DNA and DNA linearly integrated into cellular chromosomes, respectively. Virus-specific antigens in latently-infected cells include EBV nuclear antigen and membrane antigen. Latent LV is harbored in neoplastic kidney epithelial cells at temperatures $>12^{\circ}\text{C}$. The physical state of the latent virus is unknown, but it is known that membrane antigen is specified in latently infected cells. Permissive cells in vivo include essentially all cell types for HSV, epithelial cells of the nasopharynx and possibly B-lymphocytes for EBV, and neoplastic kidney epithelial cells at temperatures $<12^{\circ}\text{C}$ for LV. (42 refs)

- 79-4879 Similarities and Differences Between Various Herpesviruses: A Review. (Eng) Deinhardt, F. (Max V. Pettenkofer-Inst. Hygiene and Medical Microbiology, Univ. Munich, Munich, W. Germany); Wolf, H. *IARC Sci Publ* 24(I): 169-175; 1978.

The provisional classification of herpesviruses proposed by the Herpesvirus Study Group of the International Committee for the Nomenclature of Viruses is reviewed. Most animal species harbor their own herpesviruses of the alpha, beta, and possibly gamma groups. There is at least a partial antigenic cross-reactivity and partial DNA homology among the viruses within individual groups, whereas there are no similar relationships between the viruses of different groups. The gamma herpesviruses of primates all share some common antigen among themselves and with the human Epstein-Barr virus (EBV), they are all associated with B-lymphocytes, they do not cause lytic infections in nonlymphocytic cells, and their DNAs show a 30%-60% homology with EBV DNA. On the basis of their biological behavior, it is possible to distinguish between EBV strains which can lytically infect but not transform and those which can transform or lytically infect. Knowledge is lacking concerning the pathogenic mechanisms operative in the

different virus host-cell and virus host-organism interactions. At least part of the pathogenesis of EBV infections is certainly host and not virus controlled. (14 refs)

- 79-4880 Interaction of Oncornaviruses and Herpesviruses: A Hypothesis Proposing a Co-carcinogenic Role for Herpesviruses in Transformation -- A Review. (Eng) Hampar, B. (NCI Frederick Cancer Res. Center, Frederick, MD); Boyd, A. L. *IARC Sci Publ* 24(II): 583-589; 1978.

The interaction of herpesviruses and oncornaviruses and the role of C-type viruses in malignant transformation by herpesviruses are reviewed. Based on studies of BALB/c cells infected with herpes simplex virus (HSV), any oncogenic potential of HSV can best be explained by its role as a cocarcinogen. It is suggested that transformation by HSV and other putative cocarcinogens occurs in a manner similar to, if not identical to, spontaneous transformation. Two components are hypothesized as essential for transformation by cocarcinogens: an available genome for integration, and an accessible site for its integration into the cell genome. The cocarcinogen is postulated to induce repairable damage to the cell DNA, making sites accessible for integration of the type-C genome. Transformation of cells not actively producing type-C virus would require that the cocarcinogen induce both type-C virus synthesis and repairable DNA damage. Transformation by UV-irradiated HSV was studied in vitro using BALB/c cells. Activation of type-C virus by UV-irradiated HSV occurred at a frequency of approx $1-5 \times 10^5$. Transformation was observed only in cultures with activated type-C virus, and it occurred in a gradual and stepwise fashion. Periodic testing of transformed cells showed no evidence of spontaneous synthesis of an ecotropic type-C virus capable of forming a chronic infection. HSV antigens were demonstrated in the transformed cells by the fluorescent antibody method. (16 refs)

- 79-4881 Herpesvirus-associated Epidermal Hyperplasia in Fish (Carp). (Eng) Sonstegard, R. A. (Dept. Microbiology, Univ. Guelph, Guelph, Ontario, Canada); Sonstegard, K. S. *IARC Sci Publ* 24(II): 863-868; 1978.

The occurrence of herpesvirus-associated epithelial proliferations in carp (*Cyprinus carpio*) is reviewed. The tumors, which appear to be benign, are found on the skin, fins, eyes, and gills. Large numbers of herpesviruslike particles have been found associated with the proliferations, and the tumors are readily transmitted by rubbing tumor tissue against abraded epithelium of normal carp or by holding normal carp in the same tank as infected fish. No evidence of in vitro transformation has been detected in established fish cell lines, and attempts to establish a cell

line from the tumor cells have been unsuccessful. A similar tumor has also been described in European carp and in feral and laboratory-infected carp-goldfish hybrids, but there is no evidence that the tumor has spread to other North American fish species. The disease provides a unique opportunity to study genetic "drift" in herpesvirus. (14 refs)

- 79-4882 Co-carcinogenic Events in Herpesvirus Oncogenesis: A Review. (Eng) de The, G. (International Agency Res. Cancer, Lyon, France). *IARC Sci Publ* 24(II): 933-945; 1978.

Cocarcinogenic events in herpesvirus oncogenesis are reviewed. Both genetic and environmental factors play a determining role in the naturally occurring frog and chicken herpesvirus-associated tumors. Cofactors affecting the development of renal carcinomas in leopard frogs are temperature, degree of crowding, and age at the time of infection. Marek's disease (MD) in chickens is influenced by genetic constitution of the bird, sex, age at infection, stress, coccidiosis, and possibly avian oncornaviruses. MD viruses differ in oncogenic potential, natural infection with an apathogenic virus providing protection against later exposure to a pathogenic strain. Cell-mediated immunity appears to control the resistance of mice to herpes simplex virus (HSV) infection, resistance being a dominant trait. The most critical factor in oncogenesis by herpesvirus ateles (HVA) and herpesvirus saimiri in other than their natural hosts also appears to be genetically determined resistance or susceptibility. Three human tumors are associated with herpesviruses: cervical carcinoma (HSV type 2), Burkitt's lymphoma [Epstein-Barr virus (EBV)], and nasopharyngeal carcinoma (EBV). Malaria is also implicated in the etiology of Burkitt's lymphoma, and genetic factors or chemical carcinogens may play a role in nasopharyngeal carcinoma. (41 refs)

- 79-4883 Summary of Research in Primate Oncogenic Herpesviruses. (Eng) Deinhardt, F. (Max v. Pettenkofer-Inst. Hygiene and Medical Microbiology, Univ. Munich, Munich, W. Germany). *IARC Sci Publ* 24(II): 1087-1088; 1978.

Two groups of oncogenic simian herpesviruses have been identified to date. Both the Epstein-Barr virus-like viruses, restricted to Old-World nonhuman primates and always associated with B-lymphocyte markers, and the herpesviruses of New-World monkeys, associated with T-cell markers, are nononcogenic in their natural hosts but induce lymphoproliferative disease in related species. High priority areas for future research are listed, and the problems involved in procuring experimental animals are discussed. (no refs)

- 79-4884 Cell-Free Systems for In Vitro Translation of Herpes Simplex Virus Messenger RNA. (Eng) Preston, C. M. (Medical Res. Council, Inst. Virology, Glasgow, Scotland). *IARC Sci Publ* 24(I): 347-351; 1978.

A cell-free system active in translation of HSV (herpes simplex virus) messenger RNA was obtained by fractionation of reticulocyte lysates. Polysomes engaged in protein synthesis were removed from the lysate by rapid centrifugation; the supernatant from this procedure was concentrated by precipitation at pH 5, and ribosomal salt-wash proteins were added to the pH 5 fraction. Endogenous protein synthesis was further reduced by preincubation with micrococcal nuclease, although this treatment did not affect the translation of infected (or uninfected) BHK cell RNA. Polypeptides synthesized by the fractionated reticulocyte cell-free system were very similar to those produced by unfractionated reticulocyte lysates. (6 refs)

- 79-4885 Human Herpesvirus 1 as a Model of Regulation of Herpesvirus Macromolecular Metabolism: A Review. (Eng) Roizman, B. (Marjorie B. Kovler Viral Oncology Labs., Univ. Chicago, Chicago, IL); Morse, L. S. *IARC Sci Publ* 24(I): 269-297; 1978.

The replication of herpesviruses, particularly regulation of the viral gene product synthesis of herpes simplex viruses (HSV) types 1 and 2, is reviewed. The major criterion for defining polypeptides (pp's) as virus-specific is that their rate of synthesis increases after infection. Current evidence indicates that viral pp's form at least three groups (α , β , and γ) whose synthesis is coordinately regulated and sequentially ordered in a cascade fashion. The structural (virion) pp's comprise the largest and perhaps only component of the γ group. The synthesis of α pp's appears to require only the presence of DNA capable of initiating infection in permissive cells. The transition from α to β pp synthesis requires de novo transcription of viral DNA and the participation of functional α pp's; the synthesis of α pp terminates in the cytoplasm and requires functional β pp's. α and β messenger RNA do not compete for a common cytoplasmic factor, since the synthesis of the corresponding pp's is not mutually exclusive. The requirements for the transition from β to γ pp synthesis are similar to those for α to β . Viral DNA appears to be transcribed principally by host RNA polymerase II. The extent of transcription appears to be under some temporal control, and the abundance of transcripts generated from different regions of viral DNA is also controlled. Viral pp's probably modify transcription by interacting with the template-polymerase complex. The transition from α to β to γ RNA synthesis involves (1) the appearance in the cytoplasm of RNA suitable for translation of pp's comprising the next group and a cytoplasmic event that ends the synthesis of the previous group. Possible factors regulating the translocation of the RNA to the cytoplasm are discussed. There appears to be a clear segregation of templates specifying α pp's in HSV

REVIEW

DNA, whereas the templates for β and γ pp's appear to be randomly distributed. (64 refs)

- 79-4886 Herpesvirus in Humans. (Ger) Conner, B. (Medical Microbiology Dept., Ohio State Univ. Coll. Medicine, Columbus, OH 43210); Glaser, R. *Hautarzt* 30(6): 331-336; 1979.

Herpesviruses that cause diseases in humans (herpes simplex, varicella zoster, cytomegalovirus, and Epstein-Barr virus) share several characteristics, such as the ability to be latent and, later, reactivated and to cause immune reactions during the entire life-span of the host. These viruses have been implicated in the etiology of some malignant diseases. Attenuated viruses prepared for use in vaccinations may retain their oncogenicity. (32 refs)

- 79-4887 Characterization of Human Varicella-Zoster Virus DNA. (Eng) Hyman, R. W. (Dept. Microbiology, Milton S. Hershey Medical Center, Pennsylvania State Univ. Coll. Medicine, Hershey, PA); Iltis, J. P.; Oakes, J. E.; Rapp, F. *IARC Sci Publ* 24(1): 87-96; 1978.

The DNA of varicella-zoster virus (VZV) was isolated from infected hamster embryo lung cells by release into the Hirt supernatant and characterized by sucrose gradient sedimentation, restriction enzyme cleavage with either *EcoRI* or *HindIII* site-specific endonucleases, and by isopycnic banding in cesium chloride. The DNA's from different clinical isolates were compared. DNA's from VZV's isolated from either varicella or herpes zoster were indistinguishable on the basis of size and restriction enzyme cleavage pattern. The most important finding was that the buoyant density in cesium chloride of the VZV DNA isolated from varicella was reproducibly slightly lower than that of the VZV DNA isolated from herpes zoster. - 79-4888 Elusive Search: Do Viruses Cause Human Cancer? (Eng) Consigli, R. A. (Div. Biology, Kansas State Univ., Kansas City, KS); Center, M. *J Kans Med Soc* 80(6): 341-342; 1979.

Evidence for and against the involvement of viruses in cancer etiology is reviewed. Viruses with considerable homology to simian virus 40 transform human cells in culture. Epstein-Barr virus has been found in nasopharyngeal carcinoma and Burkitt's lymphoma. Retrovirus particles have been isolated from the culture fluids of a malignant lymphoma cell line, and there is some evidence for the presence of retroviruslike particles in human mammary tumors. The greatest obstacle in proving

that a virus causes cancer are postulates requiring isolation of the agent from all infected organisms and induction of the disease in humans by a pure preparation. (no refs)

- 79-4889 Epstein-Barr Virus Genomes and their Biological Functions: A Review. (Eng) zur Hausen, H. (Institut für Virologie, Zentrum für Hygiene, Universität Freiburg, Freiburg im Breisgau, W. Germany); Fresen, K. O.; Bornkamm, G. W. *IARC Sci Publ* 24(1): 3-10; 1978.

Recent work on the organization of Epstein-Barr virus (EBV) DNA is reviewed. Multiple copies (1-200) of EBV DNA are commonly present in nonproducer cell lines transformed by this virus, and there are strain variations in different EBV isolates. The structural organization of the EBV genome derived from different cell lines remains to be elucidated. Partial denaturation mapping indicates some variability in the terminal sequences of EBV, and molecular biological studies reveal heterogeneities in DNA preparations from different EBV strains. P3HR-1 cells, at least, contain two subtypes of the EBV genome that, upon coinfection, complement each other in early antigen induction. A number of transforming EBV strains may be helper-dependent in some early and late functions and may require complementation by an as yet poorly defined component in P3HR-1 cells. (24 refs)

- 79-4890 Comparison of Humoral and Cell-mediated Responses and Virus Markers in Herpesvirus-associated Lymphomas: A Review. (Eng) Klein, G. (Dept. Tumor Biology, Karolinska Institutet, Stockholm, Sweden). *IARC Sci Publ* 24(11): 815-833; 1978.

The humoral and cell-mediated responses and virus markers in herpesvirus-associated lymphomas are reviewed. There is evidence that the Epstein-Barr virus (EBV) receptor is restricted to B lymphocytes and is either identical to or sterically closely associated with the C3 receptor of this particular target. However, there is no relationship between C3-binding and EBV-binding activities per se. It is possible that there is some relationship between the attachment of EBV to the EBV/C3 receptor and its action as a B-lymphocyte activating agent. In addition to viral antigen induction, with EB nuclear antigen as the main marker, EBV also induces profound changes in cellular behavior and biology. Serologically detectable, disease-related changes are largely restricted to the membrane antigen (MA) and early antigen (EA) complexes of the EBV system. MA/antibody complexes may be related to the risk of recurrence of disease. Anti-MA antibodies may act directly on their targets or via an antibody-dependent lymphocytotoxicity mechanism. The lymphocyte-detected MA is a different and probably more important target. The presentation of EA to the immune system by cells involved

in the proliferative disease process appears to be important for the induction of anti-EA antibodies in ongoing, EBV-related disease. Anti-EBNA antibodies are the last to appear in the course of acute primary EBV infection. Killer T cells appear during the acute phase of infectious mononucleosis (IM) and as a small minority in Burkitt's lymphoma and nasopharyngeal carcinoma. Neither peripheral, IM-associated, nor tumor-infiltrating EBV-specific killer T cells show evidence of syngeneic (HL-A) restriction. Animal studies of major histocompatibility complex restriction suggest that the phenomenon is largely determined at the level of macrophage T-cell interaction at the time of antigen presentation. EBV-specific killer T cells are probably not responsible for the long-term control of EBV-converted B cells. In the Marek's disease virus system, T cells serve as the targets of neoplastic transformation and also appear to play a role in host defense. (69 refs)

- 79-4891 Transformation of Lymphoid Cells by Herpesviruses: A Review with Special Reference to the Phenotypic Properties of Transformed Cells. (Eng) Nilsson, K. (Dept. Tumor Biology, Wallenberg Lab., Univ. Uppsala, Uppsala, Sweden). *IARC Sci Publ* 24(1): 451-472; 1978.

The in vitro transformation of lymphocytes by herpesviruses, particularly Epstein-Barr virus (EBV), is reviewed. EBV is a lymphotropic virus in vitro, its principal target cell being an EBV receptor- and complement receptor-expressing B lymphocyte. Lymphocytes from nonprimate species are resistant to EBV infection. Most of the cells from EBV-carrying lymphoblastoid cell lines (LCL) are derived from cells infected in vitro, the interaction between virus and host cell genomes in these cells being such that virus replication is prevented. LCL and Burkitt's lymphoma (BL) lines typically contain 10-100 copies of the EBV genome. Several antigenic changes have been detected in lymphocytes immortalized by EBV, but even in most producer lines the fraction of cells replicating virus is very small. The BL cell generally resembles a resting B lymphocyte, whereas the LCL cell has many similarities to mitogen-stimulated B lymphoblasts. LCL are normal diploid cells that are nontumorigenic in nude mice, whereas BL lines are aneuploid and tumorigenic. The cell lines also differ in their surface glycoprotein patterns. Herpesvirus papio and the chimpanzee agent seem to be closely related to EBV, and the lymphoid cell lines carrying these viruses are similar to those of human EBV-carrying lines, especially the LCL type. Thus, these viruses may be better models for the study of EBV-associated diseases in humans than herpesvirus saimiri, herpesvirus ateles, or Marek's disease virus. (108 refs)

- 79-4892 The Role of Herpes and Papilloma Viruses in Human Tumors. (Ger) zur Hausen, H.

(Institut für Virologie, Zentrum für Hygiene der Universität, Hermann-Herder-Str. 11, D-7800 Freiburg, W. Germany). *Munch Med Wochenschr* 121(24): 811-812; 1979.

Studies of the role of herpes and papilloma viruses in human tumors are reviewed. Epstein-Barr virus plays a role in Burkitt's lymphoma (BL) and nasopharyngeal carcinoma (NPC), but the nature of its role is not yet known. The role of herpes simplex virus type 2 in carcinoma of the vulva, uterine cervix, and penis and the role of papilloma virus in condyloma acuminata are also unclear. Transformation of epidermodysplasia verruciformis into squamous epithelial carcinoma in light-exposed areas is observed only in warts caused by a certain type of human papilloma virus. (2 refs)

- 79-4893 Integration of Epstein-Barr Virus DNA. (Eng) Lindahl, T. (Dept. Chemistry and Tumor Biology, Karolinska Institutet, Stockholm, Sweden); Adams, A.; Andersson-Anvret, M.; Falk, L. *IARC Sci Publ* 24(1): 113-123; 1978.

Techniques that have been employed to study integration of tumor virus DNA are reviewed and their potential application to Epstein-Barr virus (EBV)-transformed cells is discussed. Sucrose gradient or glycerol gradient centrifugation provided early evidence for the existence of nonintegrated EBV DNA in transformed cells, but not for covalently closed circular EBV DNA or integrated EBV DNA. Neutral cesium chloride density-gradient centrifugation is the best technique presently available to analyze EBV DNA integration. Alkaline cesium chloride density-gradient centrifugation is a less satisfactory technique. Centrifugation in cesium chloride gradients containing antibiotics or dyes seems useful for verifying results obtained by regular cesium chloride density-gradient centrifugation and for demonstrating that the integrated EBV DNA exhibits unusual banding properties. The Hirt fractionation method has been used to confirm the absence of detectable amounts of circular EBV DNA in the human lymphoma cell line AW-Ramos, which contains only one linearly integrated EBV genome-equivalent per cell. The network technique is complicated by artefacts but may be used to yield information similar to that provided by the Hirt technique. Other methods include determination of the fate of parental virus DNA after infection, and restriction endonuclease treatment of DNA from virus-transformed cells followed by gel electrophoresis. There is a shortage of good methods to analyze integration of high mol wt viral DNA. Integrated EBV DNA has been found in Burkitt's lymphoma-derived cell lines, but its significance in relation to the "transformed state" of cells is unclear. (40 refs)

- 79-4894 The Epstein-Barr Virus. (Eng) Henle, W. (No affiliation given). Henle, G.; Lennette, E. T. *Sci Am* 241(1): 48-59, 162; 1979.

The prime candidate for a virus involved in human cancer is Epstein-Barr virus (EBV). EBV has been observed in Burkitt's lymphoma (BL) cells, and the antibody (Ab) titer to EBV in children with BL is eight- to tenfold higher than that in healthy children. EBV also appears to be intimately associated with nasopharyngeal carcinoma (NPC), and it is unequivocally the etiologic agent for infectious mononucleosis (IM). After EBV infection, the virus persists in a latent stage in the B lymphocytes, and it is periodically activated and released in the saliva. EBV has been shown to transform human B lymphocytes in vitro and in vivo. EB nuclear antigen (Ag) is the only Ag present in EBV-infected nonproducer cells. When such cells are induced to enter the lytic cycle, several additional Ag's are produced and progeny virus particles are liberated. The sequence of events following infection with EBV in humans is less clear, as is the significance of observed differences in the Ab profiles of infants and adults with EBV infections. The case for a causal relationship between EBV and BL and NPC is reviewed. About 80% of American and 2% of African cases of BL are not associated with EBV, but it is likely that when the virus is present, it is either a primary or priming factor in the disease. (no refs)

79-4895 Infectious Mononucleosis. (Eng) Rodriguez-Lopez, F. (Dept. Pediatrics, Sch. Medicine, Univ. Murcia, Murcia, Spain). *Paediatrician* 8(1/2): 48-55; 1979.

The etiology, pathogenesis, epidemiology, diagnosis, complications, and treatment of infectious mononucleosis are reviewed. The discovery of antibodies against Epstein-Barr virus in patients with mononucleosis confirmed its viral etiology and demonstrated a relationship between infectious mononucleosis and Burkitt's lymphoma. (9 refs)

79-4896 Pathogenesis of Infectious Mononucleosis. Burkitt's Lymphoma and Nasopharyngeal Carcinoma: A Unified Scheme. (Eng) Pagano, J. S. (Cancer Res. Center, Univ. North Carolina, Chapel Hill, NC); Okasinski, G. F. *IARC Sci Publ* 24(II): 687-697; 1978.

The pathogenesis of infectious mononucleosis (IM), Burkitt's lymphoma (BL), and nasopharyngeal carcinoma (NPC) is reviewed and a unified scheme presented. In NPC, infection with Epstein-Barr virus (EBV) probably begins in the throat. Replication would proceed after circulation of the linear EBV genome; and in some cases, replication of the circular DNA template would become arrested, and the EBV plasmid would become established. A plasmid-bearing epithelial cell may be the nonmalignant progenitor of NPC. The final step probably involves insertions of EBV genes that code for transforming functions. The genetic predisposition to this malignancy may be

evidenced in a kinetic rather than a mechanistic fashion. In BL, EBV in epithelial cells would move to lymphoid cells after being shed in the mid-pharynx. This is the nonmalignant phase of the infection, with the infected lymphoid cell as the progenitor of BL. After the insertions of specific EBV genes have occurred, a monoclonal malignant transformation might ensue. Geographical rather than genetic events dispose to the ultimate outcome of the lymphoma; in addition, a failure of specific cell-mediated immunity almost certainly affects lymphoma development. Primary infection of epithelial cells and secondary infection of B-lymphocytes also occurs in IM. The viral DNA forms the EBV plasmid and induces a cellular proliferation of the B-lymphocytes which resembles malignant transformation. Random insertions of pieces of EBV DNA in the cellular DNA probably occur. The distinction between transformed (BL) and proliferating (IM) cells might have a basis in the function of the plasmid, with IM cells under its direction and BL cells under the direction of the inserted genes. Based on this scheme, one might predict that other malignancies whose association with EBV is as yet unrecognized may exist. (47 refs)

79-4897 Portraits of Viruses: The Poxviruses. (Eng) Fenner, F. (Centre Resource and Environmental Studies, Australian Natl. Univ., PO Box 4, Canberra, ACT 2600, Australia). *Intervirology* 11(3): 137-157; 1979.

This review of the use of poxviruses in the development of virology includes the classification and nomenclature of viruses, the particulate nature of viruses, the morphology and chemistry of animal viruses, the artificial propagation of animal viruses, the assay of viral infectivity, reactivation and intramolecular recombination, inclusion bodies and viral carcinogenesis, the pathogenesis of generalized viral infections, humoral and cell-mediated immunity, myxomatosis of rabbits, and the irradiation of smallpox. For a period in the 1930's and again in the 1960's, poxviruses were used as tumor-producing agents in studies of carcinogenesis. (156 refs)

79-4898 Hepatitis B Virus and Hepatocellular Carcinoma (Letter to Editor). (Eng) Trichopoulos, D. (Dept. Hygiene and Epidemiology, Univ. Athens Medical Sch., Goudi, Athens 609, Greece). *Lancet* 1(8127): 1192; 1979.

Several points in a previous paper on the association between hepatitis B virus (HBV) and hepatocellular carcinoma (HCC) are clarified. The purpose of the paper was to evaluate the association of HBV with HCC in general, rather than with specific subgroups of it (ie, HCC with underlying alcoholic cirrhosis). If HBV causes cirrhosis and cirrhosis leads to HCC, it is indeed sufficient reason to indict HBV as a cause of HCC, as most epidemiologists would agree. (7 refs)

LIBRARY H. OF I. URBANA - CHICAGO

- 79-4899 Retrodifferentiation and the Fetal Patterns of Gene Expression in Cancer. (Eng) Uriel, J. (Institut de Recherches Scientifiques sur le Cancer, B. P. 8, 94800 Villejuif, France). *Adv Cancer Res* 29: 127-174; 1979.

Retrodifferentiation (RD) and fetal patterns of gene expression in cancer are reviewed. Fetal patterns in malignant tumors (tumor-associated antigens, enzyme activities and metabolic changes, isozymes, and morphologic and structure-dependent properties), fetal patterns in non-cancerous growth (fetal antigens in regeneration, cell injury, and tissue repair, fetal isozymic transitions, and morphologic changes), the plasticity of the differentiated state (differentiation vs RD, differentiation of malignant cells, RD in cell injury and tissue repair, and RD in normal and transformed cells in vitro), and RD and cancer are the topics covered. It appears that RD is a physiological and common adaptive process for the maintenance of cell integrity against deleterious agents (physical, chemical, and viral). In physiological conditions, RD is counterbalanced by redifferentiation. The studies reviewed suggest that the resemblance between many cancerous and embryo-fetal cells is significant, since it stems from the convergence of common antigenic, biochemical, morphologic, and behavioral properties; that the resemblance is, nevertheless, not specific to neoplasia but is also seen in some noncancerous cells; and that RD seems to be a unique mechanism of cell rejuvenation underlying neoplastic development and regenerative processes. It is emphasized that many properties of cancerous cells may result in part from an adaptive process against deleterious internal factors (aging, abnormal metabolism, or biosynthetic errors) or noxious external agents (chemical, physical, viral, or mutational) and that RD appears to be the most efficient mechanism underlying the adaptive process. - 79-4900 Neoplasias and B-Cell Precursors. (Eng) Seligmann, M. (INSERM Unit Immunopathology, Hopital Saint Louis, Paris, France). *Nature* 279(5714): 578; 1979.

Various studies suggest that clonal diversification is accomplished by the pre-B-cell stage in the B-cell differentiation pathway. In myeloma patients, antibodies specific for idiotypic determinants of the myeloma globulin stain bone marrow cells with pre-B-cell characteristics, which provides evidence that pre-B cells belong to the neoplastic clone. Some murine and human neoplasias involve early B-cell precursors that produce cytoplasmic immunoglobulin in the absence of membrane-bound immunoglobulin molecules. (16 refs)

- 79-4901 Hairy-Cell Leukemia. (Ita) Carbone, A. (Istituto di Anatomia, Università Cattolica del

Sacro Cuore, Rome, Italy); Lauriola, L.; Piantelli, M.; Salsano, F.; Mango, G.; Musiani, P. *Recent Prog Med* 66(4): 370-381; 1979.

The recent literature on hairy cell leukemia (HCL) is reviewed. HCL affects mainly adults above 50 yr; the men-to-women ratio is 4:1. Splenomegaly is always present, and moderate hepatomegaly is seen in about half of all cases. Lymph node involvement is rare. Pancytopenia, normocytic and normochromic anemia, and hairy cells accounting for 15%-90% of the WBC are characteristic of HCL. The hairy cells possess intrinsic membrane immunoglobulins. The response of hairy cells to mitogens (phytohemagglutinin concanavalin A, and pokeweed mitogen) is reduced compared to normal controls. The findings indicate the B-lymphocyte nature of HCL. (40 refs)

- 79-4902 Influence of the Major Histocompatibility Complex on T-Cell Activation. (Eng) Miller, J. F. (Walter and Eliza Hall Inst. Medical Res., Post Office Royal Melbourne Hosp., Victoria, Australia). *Adv Cancer Res* 29: 1-44; 1979.

The effects of the major histocompatibility complex (MHC) gene products on T lymphocytes and on tumor resistance are reviewed. The MHC-linked *Ir* genes control T-cell activities and T-cell-dependent functions, and the reactivities of various T-cell subsets are restricted by distinct MHC genes. I-region gene products govern the immune responses of helper T cells and T cells involved in delayed hypersensitivity to antigens presented by macrophages and B cells. H-2K and H-2D gene products influence the response of T cells that are directly cytotoxic and that play an essential role in resistance to virus infections. The exact manner by which the MHC produces such effects is not known, but several possible mechanisms have been proposed. One suggestion is that MHC gene products are intimately involved in delivering an activating signal to T cells. Only antigenic determinants able to associate with such products would be immunogenic. The existence of several MHC gene loci and of multiple allelism at each locus will ensure effective association of antigenic determinants with MHC gene products in most members of a given species. Polymorphism thus allows most individuals to respond adequately to one or other determinant of a complex antigen. (150 refs)

- 79-4903 Suppressor Cells: Permitters and Promoters of Malignancy? (Eng) Naor, D. (Lautenberg Center for General and Tumor Immunology, Hebrew Univ.--Hadassah Medical Sch., Jerusalem, Israel). *Adv Cancer Res* 29: 45-125; 1979.

The role of suppressor (SP) cells in the development of malignancy is reviewed. Studies demonstrating the

augmentation of antitumor responses in experimental immunocrippled animals (adult thymectomized, splenectomized, x-irradiated, or antithymocyte serum-inoculated) are described briefly. Most of these studies were performed before the function of SP cells was recognized, but a retrospective picture of these findings may be interesting, since at least part of the results may be interpreted differently if the function of the SP cell is taken into account. The possibility that SP cells are the initiators of immunostimulation and sneaking through phenomena is also surveyed. More-direct experimental evidence showing the effect of specific and nonspecific SP cells on the relationships between the tumor and host immune system is presented. For the most part, the effect of SP cells on syngeneic tumors and, occasionally, on nonspecific tumor cells is covered. Nonspecific neoplastic cells cannot stimulate a detectable allogeneic immune response after inoculation into an allogeneic host, and they can grow progressively in such an environment. SP cells are classified arbitrarily into permissive SP cells, which populate the host before its confrontation with the tumor, and promoter SP cells, which are induced by the tumor. Finally, chemical, physical, and biological properties of these SP cells are described, and various means for their selective elimination are offered. SP cells can be eliminated from potential or actual tumor-bearing hosts by adult thymectomy, splenectomy, or hydrocortisone acetate or antithymocyte serum treatment, but these methods may induce a general autoimmune response in addition to antitumor activity. (230 refs)

- 79-4904 Immunosuppression in Clinical Organ Grafting. (Eng) Calne, R. Y. (Dept. Surgery, Univ. Cambridge Clinical Sch., Hills Road, Cambridge CB2 2QQ, England). *Trends Pharmacol Sci* 1(Inaug. Issue): 21-22; 1979.

A new immunosuppressive drug currently being tested is Cyclosporin A (CyA), a cyclic fungal peptide of 11 amino acids, 1 of which is unique. Apparently, it acts in a manner completely different from that of any other immunosuppressive drug. It affects proliferating T cells, and the serum of treated animals and patients inhibits phytohemagglutinin transformation and mixed lymphocyte culture responses. It is not known why CyA is so specific in affecting transforming lymphocytes. (18 refs)

- 79-4905 Concanavalin A Receptors on the Surface Membrane of Lymphocytes from Patients with Burkitt's Lymphoma, Other Malignant Lymphomas, Leukaemia and Lymphoma Cell Lines. (Eng) Ben-Bassat, H. (Chanock Center Virology, Hebrew Univ.-Hadassah Medical Sch., Jerusalem, Israel); Goldblum, N. *IARC Sci Publ* 24(11): 639-647; 1978.

The mobility of concanavalin A (Con A) receptor sites on

lymphocytes from patients with malignant lymphomas and chronic lymphocytic leukemia (CLL) was studied. Lymphocytes from the peripheral blood and tumor tissues of patients with African Burkitt's lymphoma (BL) showed reduced cap-forming ability and increased agglutinability in response to con A, compared with normal lymphocytes. Blood lymphocytes from patients with CLL, Hodgkin's disease, and other malignant lymphomas showed a similar reduction in cap formation and increase in agglutination, compared with lymphocytes from normal subjects, patients with carcinoma, and patients with nonmalignant disorders. The cap formation of lymphocytes from a healthy donor or a lymphoma patient was independent of the source from which the cells were isolated, eg, lymph-node, spleen or blood. Lymphoma cell lines established from tumors of BL patients and lymphoblastoid cell lines originating from other sources also exhibited an increased agglutination and reduced cap formation with con A. Further studies indicated that Epstein-Barr virus-positive human lymphoid lines had a lower cap-forming ability than virus-negative lines. (12 refs)

- 79-4906 Second Malignant Neoplasms in Hodgkin's Disease. (Eng) Getaz, E. P. (S. E. Massachusetts Medical Associates, 322 E. Center St., W. Bridgewater, MA 02379). *Cancer Chemother Pharmacol* 2(3): 143-145; 1979.

The prolonged survival of patients with Hodgkin's disease (HD) brought about by combined chemotherapy (approx 75% of all patients with advanced HD achieve complete remission) has led to the recognition of an increased risk of second tumor induction. The features of this induction are reviewed. The severe depression of cellular immunity that accompanies HD may be a contributing factor in the development of subsequent neoplasms. A variety of second tumors in HD patients has been documented, but their possible significance was overlooked because the incidences of the tumors (apart from skin tumors) seemed no greater than those expected in the general population. More recent reports have shown significant incidences of acute nonlymphocytic leukemia and anaplastic carcinoma of the thyroid in HD patients, and there is also an unexplained increase in Kaposi's sarcoma. The etiology of second malignancies is multifactorial. The effects of immunosuppressive treatment for HD augments the patients' own impaired cellular immunity, providing a receptive milieu for the oncogenic effects of radiation and chemotherapeutic agents. The incidence of second tumors is also related to the intensity of HD treatment, except for thyroid carcinomas, in which the response may be biphasic. (37 refs)

- 79-4907 Immunology of Rat Hepatic Neoplasia. (Eng) Baldwin, R. W. (Cancer Res. Labs., Univ. Nottingham, Nottingham, England). *Prog Biochem Pharmacol* 14: 109-122; 1978.

The immunology of rat hepatic cancer is reviewed. Carcinogen-induced rat hepatic neoplasms express a variety of neoantigens, the most consistently demonstrable components being the tumor-associated embryonic antigens. These have been demonstrated on all of the hepatic tumors analyzed so far, including both primary and transplanted tumors induced with aminoazo dyes and 2-acetylaminofluorene-induced tumors. Typing of these antigens may provide suitable methods for characterizing transformed cells. Antigen assay may also provide simple screening systems for the preliminary evaluation of chemical carcinogens. The most significant characteristic of carcinogen-induced tumors is the expression of tumor-specific cell surface antigens that may function as tumor-rejection antigens. This type of neoantigen is not always expressed on transformed cells, however. These neoantigens are highly polymorphic and, in most instances, it has been shown that tumors express individually distinct components. The tumor cell surface products may be modified histocompatibility antigens. It is suggested that they can be utilized for the analysis of "mutationlike" events in hepatocarcinogenesis. (50 refs)

- 79-4908 **The Micronucleus Test: Statistical Design and Analysis.** (Eng) Mackey, B. E. (U.S. Dept. Agriculture, Science and Education Admin., Western Regional Res. Center, Berkeley, CA 94710); MacGregor, J. T. *Mutat Res* 64(3): 195-204; 1979.

The micronucleus test has become a widely used screening procedure for the in vivo detection of chromosome breakage or loss induced in bone marrow erythroblasts by chemical mutagens. Little attention has been given to the statistical design of experiments employing this test. A sequential statistical analysis based on the negative binomial distribution is described. It permits the investigator to optimize the number of animals per test group and the number of cells analyzed per animal. The test will detect a predetermined increase in the incidence of micronucleated cells over that observed in the control population with chosen limits of probability of type I (α) and type II (β) error. In this case, α is the probability of declaring that a compound is mutagenic when it is not, and β is the probability of not declaring that a compound is mutagenic when, in fact, it is. The sequential test is slightly more powerful than a one-stage test based on the same distribution, and it would require less animals. An alternative sequential approach based on the binomial distribution is presented that is applicable when the number of cells analyzed per animal is variable. (10 refs)

- 79-4909 **Genes, Pollutants and Human Diseases.** (Eng) Trosko, J. E. (Dept. Human Development, Coll. Human Medicine, Michigan State Univ., East Lansing, MI 48824); Chang, C. C. *Q Rev Biophys* 11(4): 603-627; 1978.

Some of the basic concepts related to disease are examined using cancer as a model. The nature of carcinogenesis; the multistage nature of cancer and other chronic diseases; classes of genetic and environmental factors in carcinogenesis; chemical modification of the extent of DNA damage; chemicals that can modify DNA repair; chemical modification of the expression of genetic damage and its possible role in carcinogenesis; and genes, chemical pollutants, mutations, and evolution are discussed. Although attempts should be made to minimize human exposure to environmental pollutants which could induce mutations, it will never be possible to prevent mutations from occurring in some cells. Although initiating and promoting chemicals should be identified, it may be impossible to label a compound as dangerous or safe without considering the total context of the organism-chemical interaction. (116 refs)

- 79-4910 **Ribosome Accumulation and the Regulation of Epidermal Hyperplastic Growth.** (Eng) Argyris, T. S. (Dept. Pathology, SUNY Upstate Medical Center, Syracuse, NY 13210). *Life Sci* 24: 1137-1147; 1979.

The role of ribosomes in the regulation of epidermal hyperplastic growth (EHG) is reviewed. Ribosomes accumulate in large numbers during EHG, and their number returns to normal levels during the regression period, when the hyperplastic epidermis returns to its normal size. There is a rough correlation between the degree of EHG and the amount of ribosome accumulation in each epidermal cell. Elevated ribosome levels are also seen in chronic epidermal hyperplasia and in epidermal papillomas. It is suggested that the marked accumulation of ribosomes in epidermal cells, as well as other as yet unspecified linked molecular changes, produce an imbalance that keeps epidermal cells proliferating, resulting in hyperplastic growth. In epidermal tumors, this imbalance is locked in place, resulting in a permanent EHG condition. (31 refs)

- 79-4911 **Differences in Susceptibility to Herpes Simplex Virus Infection of Inbred Strains of Mice.** (Eng) Kirchner, H. (Inst. für Virusforschung, Deutsches Krebsforschungszentrum, Heidelberg, W. Germany); Kochen, M.; Munk, K.; Hirt, H. M. *IARC Sci Publ* 24(11): 783-788; 1978.

Marked differences were observed between the susceptibility of adult C57BL/6 mice to infection with herpes simplex virus (HSV)-1. These differences were seen after various infection schedules but were most marked after ip infection. A significant difference between the LD₅₀ after ip infection was also observed between LPS(lipopolysaccharide)-resistant C3H/HeJ and the closely related LPS-sensitive C3HeB/FeJ mice. Injection of LPS significantly increased

the LD₅₀ after ip infection with HSV in C57BL/6 or C3H/HeJ mice but not in C3HeB/FeJ mice. In vitro pretreatment with LPS was necessary to demonstrate replication of HSV in mouse spleen-cell cultures. Such replication could be demonstrated in cultures of DBA/2 and C3HeB/FeJ but not in C57BL/6 or C3H/HeJ mice. (11 refs)

- 79-4912 Apudomas (First of Two Parts). (Spa) Varas Lorenzo, M. J. (Barcelona, Spain). *Rev Esp Enferm Apar Dig* 55(1): 89-98; 1979.

Literature on the embryological, endocrinological, and biochemical aspects of apudomas is reviewed. The apudomas were classified as orthoendocrine tumors, paraendocrine tumors, and multiple endocrine adenomatosis. (no refs)

- 79-4913 Histogenesis and Morphology of Colorectal Carcinoma. (Ger) Thurner, J. (Pathologisch-anatomisches Institut, Landeskrankenanstalten Salzburg, Mullner Hauptstrasse 48, A-5020 Salzburg, Austria). *Wien Med Wochenschr* 129(10): 264-267; 1979.

The histogenetic and morphological aspects of colorectal carcinoma (CRC) are reviewed. At least half of all CRC's can be assumed to originate from neoplastic polyps. There is a clear relationship between the diameter of these polyps and the percentage of malignant transformation: 1% of all polyps measuring up to 10 mm in diameter are malignant, but >50% of the polyps >20 mm in diameter are malignant. About 70% of the neoplastic polyps are adenomatous polyps. Along with neoplastic polyps, certain intestinal polyposes (familial colonic polyposis, Gardner's syndrome, Turcot syndrome, and Peutz-Jeghers syndrome) and ulcerative colitis are considered the precursor stages of CRC. The majority of the CRC's are located in the rectum and sigmoid colon, and >80% are adenocarcinomas. The recent considerable increase in the incidence of CRC is attributed to exogenous causes such as increased fat consumption, which leads to increased secretion of coprostanol, coprostanone, bile acids, and total bile steroids and also to a change in the intestinal flora. There are racial but no geographic differences in incidence. The incidence is highest in the age bracket 60-70 yr. (25 refs)

- 79-4914 Origin and Dissemination of Human Urinary Bladder Carcinoma. (Eng) Weinstein, R. S. (Department of Pathology, Rush-Presbyterian-St. Luke's Medical Center, 1753 W. Congress Parkway, Chicago, IL 60612). *Semin Oncol* 6(2): 149-156; 1979.

The origin and dissemination of human urinary bladder

carcinoma (BC) are reviewed. Human BC has an unpredictable course with respect to progression and recurrence, influenced perhaps by tumor-cell properties, host-tumor relationships, responses to therapy, and the coexistence of carcinoma in situ and solid bladder tumors in some patients. The clonality of human BC is uncertain, although evidence for monoclonal origin for most human tumors is accumulating. If human BC is monoclonal in origin, then multifocal lesions might be the result of dissemination of tumor cells in the bladder. Intra-epithelial dissemination may be an important feature of human BC, although it is not a certainty. Malignant cells may migrate laterally within the epithelium or may slough into the urinary space and be seeded onto bladder epithelium at secondary locations. In the latter case, procedures that may induce injury and/or proliferation of the epithelium (such as cystoscopy) are suspect as possible agents of dissemination or recurrence. Intra-epithelial dissemination of solitary tumor cells and nests of cells (Paget's disease) can be particularly conspicuous in bladders harboring extensive carcinoma in situ. The lateral expansion of sheets of malignant cells is well described in cases of carcinoma in situ. The development of metastases from carcinomas requires the completion of a sequence of seven events; prevention of early local invasion would be the most effective preventive measure since once the BC invades the stroma, the progression of the disease is usually rapid. Several theories to explain the mechanism by which tumors invade connective tissue are detailed: the mechanical theory (an expanding tumor forces its way into alternative locations), the cell-membrane alteration theory, the increased cell motility theory (particularly ameboidlike motility), the loss of cell polarity theory (cells become susceptible to chemotactic factors in novel ways), and the theory of breakdown of natural host barriers to invasion. The early stage of tumor invasion may prove to be a multifactorial process. (91 refs)

- 79-4915 On an Article by K. M. Pozharisskii Titled "Problems Concerning the Morphogenesis of Cancer of the Rectum and Large Intestine." (Rus) Gol'bert, Z. V. (No affiliation given). *Arkhl Patol* 41(3): 56-59; 1979.

Some principles formulated in a previous article on the morphogenesis of Cancer of the rectum and large intestine are critically reviewed. The author erroneously claimed that carcinoma in situ is the early stage of development of adenocarcinoma of the rectum and large intestine, but in fact Stages I, II, and III dysplasias precede carcinoma in situ. (no refs)

- 79-4916 Expression of Differentiated Functions in Hybrid Cells. (Eng) Klein, G. (Karolinska Institutet, Stockholm, Sweden). *Differentiation* 13(1): 61-62; 1979.

Data suggesting that certain chromosome segments carry genes that are critical to the neoplastic growth of given target cells are reviewed. The precise meaning of the nonrandom chromosomal changes occurring in neoplastic cells remains to be deciphered, taking into account the evidence that malignancy generally behaves as a recessive trait. (16 refs)

- 79-4917 Chromosomal Analysis of Exposed Populations: A Review of Industrial Problems. (Eng) Purchase, I. F. (Central Toxicology Lab., ICI Ltd., Alderley Park, Nr. Macclesfield, Cheshire, England). In: *Mutagen-induced Chromosome Damage in Man. Proceedings of a Symposium held in Edinburgh, Scotland, July 7-8, 1977*. Medical Research Council (Edinburgh, Scotland): 355 pp.; 258-267; 1978.

Although chemically induced mutational effects are theoretically possible in man, no definitive data are available for determining their practical significance. Most neoplasms are associated with chromosomal abnormalities; however, it is not known whether these abnormalities are primary or secondary phenomena and whether they are involved in the initiation of the neoplastic process or are merely associated with the progression of tumor growth. Factors which can influence the results of a study of an exposed population may be unrelated to the chemical itself; technical factors, age, viral infections, duration of exposure, smoking, and variations in the level of exposure should all be considered. It has been shown that there is a close association between the clastogenic effect and the carcinogenicity of a chemical, and that there is a dose-response relationship evident in some studies of chemical clastogens. Improved methods for the identification of chemical carcinogens, determination of the 'safe' dose of a carcinogen, and continued population monitoring are advised. Individual idiosyncracies must also be considered. More rapid techniques must be developed to estimate chromosomal damage with the same degree of accuracy as the classical technique. Another major challenge for the future will be in identifying confounding effects. Emphasis should be placed on the utility of studying abnormal aberration levels as a means of solving problems associated with potential and actual occupational carcinogenesis. (48 refs)

- 79-4918 Bacteria and Cancer. (Rus) Pozharisskii, K. M. (Lab. Experimental Tumors, N. N. Petrov Res. Inst. Oncology, Leningrad, USSR). *Arkhl Patol* 41(4): 72-79; 1979.

Current literature on the role of bacteria in carcinogenesis is reviewed. Analysis of the incidence of spontaneous and carcinogen-induced tumors in germfree (GF) mice and their normal counterparts did not provide an unequivocal conclusion. There was no difference between GF and normal

NMRI/HAN mice in the frequency of lung tumors, but GF mice had a decreased frequency of mammary gland tumors and an increased frequency of tumors of the lymphoreticular system. The sc administration of methylcholanthrene induced fibrosarcomas in GF rats; dimethylbenz(a)anthracene sc induced adenocarcinomas of the mammary gland and myeloid leukemia. Epidemiological analyses have revealed a certain association between the incidence of cancer of the large intestine and the composition of the intestinal microflora. (81 refs)

- 79-4919 Alcohol as a Co-Factor in the Etiology of Cancer. (Eng) Schottenfeld, D. (Dept. Medicine, Memorial Sloan-Kettering Cancer Center, 1275 York Ave., New York, NY 10021). *Cancer* 43(5, Suppl): 1962-1966; 1979.

Alcohol and tobacco appear to act synergistically in the pathogenesis of epithelial cancers of the oropharynx (excluding lip), larynx, and esophagus. For the subsites within the upper aerodigestive tract, over 10,000 deaths in United States men during 1978 may be attributed to tobacco and alcohol consumption. The cancer sites for which tobacco and alcohol are major determinants occur with greater frequency in men, blacks, lower socioeconomic groups, and with increasing urbanization and increasing age (35-70 yr). Because primary hepatocellular carcinoma occurs more commonly in patients with cirrhosis, chronic alcohol abuse is an important risk factor for carcinoma of the liver parenchyma. Although experimental animal studies have failed to demonstrate whether ethanol can independently initiate tumorigenesis, various alternative or associated biochemical and immunological mechanisms of action have been proposed to explain the effects of alcohol consumption on cancer incidence. (39 refs)

- 79-4920 Significance of Occupational Cancer. (Eng) Boyland, E. (London Sch. Hygiene and Tropical Medicine, London WC1, England). *Prog Biochem Pharmacol* 14: 76-81; 1978.

The significance of studies of occupational cancer is surveyed. At least 90% of human cancers are due to chemical agents, and about 80% are due to environmental factors. Many causes of human cancer have been found by investigation of occupational disease, and this approach is still the most promising. Because chemical carcinogens are difficult to identify by examination of human populations, it is essential to carry out animal tests on chemicals in the environment to obtain indications of carcinogenic activity. Chemical carcinogens can be divided into two groups: the first group (eg, alkylating agents) does not require metabolic transformation for activity; the second group (eg, nitrosamines and polycyclic hydrocarbons) requires metabolic or chemical activation. The metabolic reactions

REVIEW

involved in the activation of the second group are part of the normal detoxification processes. The first step in the activation of polycyclic aromatic hydrocarbons is the formation of epoxides or arene oxides. Their action is due to the presence of an ethylene group or double bond that can be activated and to their similarity in shape to constituents of the target DNA molecule. Vinyl chloride and trichloroethylene, two other carcinogens, combine with DNA in a manner similar to that of the arene oxides of the carcinogenic hydrocarbons. Occupational cancers have special significance because they can give indications of the specific causes of cancer, and recognition of causes of cancer in workers gives indications of the causes of cancer in the general population. (no refs)

- 79-4921 Fertility of the Diethylstilbestrol-exposed Offspring. (Eng) Siegler, A. M. (Dept. Obstetrics and Gynecology, State Univ. New York, Downstate Medical Center, 450 Clarkson Ave., Brooklyn, NY 11203); Wang, C. F.; Friberg, J. *Fertil Steril* 31(6): 601-607; 1979.

The effects of diethylstilbestrol (DES) on the subsequent fertility of women exposed to the drug in utero are reviewed. Many factors enter into the evaluation of patients with a documented DES exposure. In an ongoing study with 2,940 participants collated from four regional institutions, differences were found in accordance with modes of entrance into the study and geographic differences in patterns of drug exposure such as the median dose, duration, and onset of therapy. Preliminary results seem to suggest no statistical difference in the outcome of pregnancy in DES-exposed patients, compared with controls. Normal pregnancy and delivery can occur in the presence of vaginal and cervical DES-induced abnormalities. The effect on fertility and the outcome of pregnancy still must be evaluated, and even if an abnormality is found, no therapy is indicated unless it is shown that the abnormality is responsible for the reproductive dysfunction. Seminal abnormalities noted in DES-exposed men suggest that fertility may become impaired in some individuals. (40 refs)

- 79-4922 Survival Rates after Enucleation of Eyes with Malignant Melanoma. (Eng) Seigel, D. (Office Biometry and Epidemiology, Natl. Eye Inst., NIH, Bethesda, MD 20014); Myers, M.; Ferris, F.; Steinhorn, S. C. *Am J Ophthalmol* 87(6): 761-765; 1979.

Previously published data were pooled to determine whether enucleation of the eye in patients with primary melanoma of the uvea accelerates the dissemination of tumor cells, metastases, and mortality. Death rates for eye and skin melanoma and for cancer of the larynx, stomach, cervix, corpus, and breast, at selected stages of disease and treated by surgery, radiotherapy, chemotherapy, or a com-

bination of therapies, were analyzed. A pattern of high mortality rates in the early years following diagnosis and lower rates 6-10 yr thereafter was observed. It is suggested that the small number of patients available to follow-up is probably the cause for the previously reported increase in mortality 6-10 yr after enucleation for melanoma of the uvea. Enucleation often coincides with an active phase of malignancy, during which mortality increases, causing the high death rates in the years following diagnosis. An alternative explanation is given for the occurrence of metastases after surgery. Ocular tumors are often small at the time they become symptomatic or diagnosed. Metastases from such tumors to other areas of the body are likely to be even smaller and, consequently, may be difficult to diagnose at that time. This analysis of survival rates in patients with uveal melanoma and other cancers produced no evidence to alter the existing pattern of treatment for uveal melanoma. (4 refs)

- 79-4923 Cancer, Mathematical Models and Aflatoxin. (Eng) Carlborg, F. W. (Dept. Statistics, Univ. Chicago, Chicago, IL). *Food Cosmet Toxicol* 17(2): 159-166; 1979.

Four mathematical models (probit, logit, one-hit, and improved Mantel-Bryan) used to estimate the risk of low doses of carcinogens to humans were evaluated with respect to epidemiological and experimental data on aflatoxin carcinogenesis. In a study of the incidence of liver cancer in male rats fed various doses of aflatoxin, all four models fit the data about equally well. The calculated frequencies for the one-hit model matched the observed frequencies within the limits of statistical error. There were insufficient data to carry out this analysis for the probit or logit models. Best estimates of the relationship between aflatoxin dose and lifetime risk of liver cancer in rats, and the upper 99% confidence limits from the four mathematical models for the dose-response relationship between aflatoxin intake and risk of liver cancer in rats are presented. Besides the problem of choosing the most appropriate mathematical model, three other factors influence the results: species conversion, the choice of an end-point, and species selection. The estimated concentration of ingested aflatoxin for the US population was used with each model to calculate the corresponding annual number of liver cancers due to aflatoxin among US men. (18 refs)

- 79-4924 Excess Mortality of Men in France. Analysis of Medical Causes of Deaths. (Fre) Riondet, J. (No affiliation given). *Rev Prat* 29(22): 1819-1820; 1979.

The excess cancer mortality of French men over women in the age bracket 40-60 yr is significantly higher than that in the US and, especially, in Sweden. The mortality due to

tumors of the buccal cavity, pharynx, esophagus, and larynx is 5-17 times higher than that in Sweden and 4-5 times higher than that in the US. Alcohol and smoking are considered causes of the excess cancer mortality. (2 refs)

- 79-4925 Advances in Childhood Solid Tumors. (Eng) Sinks, L. F. (Div. Pediatric and Adolescent Oncology, Vincent T. Lombardi Cancer Res. Center, Georgetown Univ. Medical Center, Washington, DC); Sumer, T. *Adv Pediatr* 25: 415-450; 1978.

Advances in the therapy of solid tumors in children and adolescents are reviewed. The tumors discussed include Wilms' tumor, rhabdomyosarcoma, osteogenic sarcoma, Ewing's sarcoma, CNS tumors, neuroblastoma, retinoblastoma, malignant ovarian tumors, testicular tumors, and hepatoblastoma. (127 refs)

- 79-4926 Controversies in Nutrition. A Brief Review. (Eng) Arlin, M. (Univ. Alaska, Anchorage, AK). *Nurs Clin North Am* 14(2): 199-214; 1979.

The possible role of nutrition in a number of diseases, including cancer, is reviewed. The varied geographic distribution of different cancers (ie, the high incidence of gastric cancer in Japan and low incidence in the US and the high incidence of colon cancer in the US and low incidence in Japan) supports a nutritional role, particularly because groups migrating to countries of high cancer incidence tend to demonstrate an increased risk within the first generation. The possible role of high dietary fat, sugar, and protein intake in colon cancer is discussed together with the current belief in the protective effect of dietary fiber. (30 refs)

- 79-4927 Mechanism of Action of Diet as a Carcinogen. (Eng) Weisburger, J. H. (Naylor Dana Inst., Valhalla, NY 10595). *Cancer* 43(5, Suppl): 1987-1995; 1979.

The mechanism of action of diet as a carcinogen is reviewed. In the United States, stomach cancer has declined over the past 50 yr and it is beginning to decline in countries where the rate is still high. It is hypothesized that gastric cancer might stem from the formation in the stomach or in pickled foods of alkylnitrosourea compounds. Vitamins C and E may inhibit this process. The risk of gastric cancer might therefore be reduced by assuring consumption of vitamin C with all meals and by reducing dietary salt. Cancers of the colon, breast, and prostate are associated with high intake of dietary fat. The actual carcinogen responsible for these cancers might be an *o*-methylarylamine obtained during the frying of protein-

containing foods. Dietary fiber, vitamin C, and selenium have been implicated as protective elements in specific types of cancer, including cancer of the colon. Vitamin A and retinoids have been observed to reduce breast and bladder carcinogenesis. (61 refs)

- 79-4928 Dietary Habits and Cancer Epidemiology. (Eng) Wynder, E. L. (American Health Foundation, 320 E. 43rd Street, New York, NY 10017). *Cancer* 43(5, Suppl): 1955-1961; 1979.

The hypothesis that specific nutritional deficiencies and unbalanced metabolism from dietary excesses are important in the etiology of many of the most common human cancers is reviewed. Alcohol and nutritional deficiencies could enhance carcinogenesis in tobacco smokers by increasing the microsomal metabolic activation of specific tobacco carcinogens. It appears to be fat and/or cholesterol in the diet which is primarily responsible for the association between diet and colon cancer. Bile acid production appears to be particularly important in colon carcinogenesis, and stool bulk may be a negative modifying factor. The fact that Finns ingest large amounts of dietary fat but have low rates of colon cancer indicates that total fat alone is not the only factor in colon carcinogenesis, however. Breast cancer also appeared to be associated with dietary fat, particularly animal fat. High rates of postmenopausal cancers may be due to increased prolactin/estrogen ratios. (58 refs)

- 79-4929 Interaction of Drugs, Hormones, and Nutrition in the Causes of Cancer. (Eng) Lipsett, M. B. (Clinical Center, NIH, Bethesda, MD 20014). *Cancer* 43(5, Suppl): 1967-1981; 1979.

Hormones may act as promoters in the carcinogenic process, and occasionally their metabolites may act as antihormones or have new physiologic effects. Drugs can interact with the endocrine system in many ways. They can promote secretion of a hormone, alter its rate of removal from plasma, change plasma protein-binding characteristics, or modify routes of metabolism. Estrogens have a preparative effect on the uterine endometrium. There are biologic, clinical and epidemiologic reasons for believing that estrogen administration to postmenopausal women increases the risk of endometrial cancer. Although there are similar biologic reasons to associate prolonged estrogenic stimulation with breast cancer, evidence for such an association is weak. Oral contraceptive use has been associated with a variety of hepatocellular tumors. Although estrogens can effect several hepatic functions, it seems likely that the 17 α -alkyl and 17 α -ethinyl functions of the progestins and estrogens are involved in this process. The role of estrogen use during pregnancy in the causation of vaginal cancer in female offspring and the role of androgens in prostate cancer are discussed. (168 refs)

REVIEW

79-4930 Dietary and Nutritional Implications in the Multifactorial Etiology of Certain Prevalent Human Cancers. (Eng) Gori, G. B. (Div. Cancer Cause and Prevention, NCI, Bethesda, MD 20014). *Cancer* 43(5, Suppl): 2151-2161; 1979.

The role of diet in the etiology of human cancers is reviewed. It has been estimated that 60% of cancers in women and 40% of those in men are related to diet and nutrition. Evidence that diet, rather than other environmental or genetic factors, is involved in the causation of cancers such as those of the breast, colon, esophagus, and pancreas comes from animal studies and studies of migrant populations and homogeneous populations living and working in the same environments. The cancers that are highly correlated with diet show a great variation in incidence around the world and changes in rates with time. It is theorized that carcinogenesis is promoted by the metabolic derivatives of bile acids, protease enzymes, antioxidant deficiency, changes in an individual's hormone profile, excess or deficient nutrient and calorie consumption, and certain food-borne carcinogens. Protease inhibitors, a variety of natural and artificial dietary antioxidants, and fiber may inhibit the carcinogenic process. Chemical compounds occurring naturally in some foods appear to inhibit carcinogenesis by increasing the activity of the mixed-function oxidase system. Certain dietary components may also enhance or inhibit the absorption of carcinogens. (100 refs)

79-4931 Oral Contraceptives and Cancer Risk. (Swe) Gustafsson, J. A. (Dept. Chemistry, Karolinska Institutet, S-104 01 Stockholm, Sweden); Hagenfeldt, K. *Lakartidningen* 76(17): 1625-1627; 1979.

Epidemiological studies on the relationship between oral contraceptives (OC) and cancer risk are reviewed. The long-term use of OC for over 2 yr is believed to reduce the risk of benign breast tumors; the protective effect of OC against such tumors persists even after cessation of use. The data available do not show conclusively whether or not OC would modify the risk of breast cancer, but some data indicate that OC can increase the risk of breast cancer in certain groups of women (young women, women with benign breast tumors, and in women who used OC before their first pregnancy). There is an increased risk of endometrial cancer in women who used sequential OC, which have been withdrawn from circulation. The epidemiological studies indicate that OC can reduce the risk of ovarian cancer and that the long-term use of OC by predisposed women can increase the risk of cervical dysplasia and carcinoma in situ of the cervix, but there is no conclusive evidence on the effect of OC on the incidence of hypophyseal adenoma and malignant melanoma. OC cause a marked increase in the relative risk of hepatocellular adenoma after long-term use (over 3 yr); the risk increases with the steroid dose, the length of treatment,

and with the age of the patient. Diethylstilbestrol, used inadvertently during pregnancy, increases the risk of vaginal neoplasia in female offspring. (1 ref)

79-4932 Estrogens and Endometrial Cancer (2 Letters to Editor). (Eng) Horwitz, R. I. (Yale Univ. Sch. Medicine, New Haven, CT 06510); Feinstein, A. R.; Jick, H.; Watkins, R. N.; Rothman, K. J.; Walker, A. M. *N Engl J Med* 300(23): 1333-1334; 1979.

A recently published conclusion that estrogens are causally related to endometrial cancer was based on unverified evidence from an inadequately controlled study. The reported reversal of damage following discontinuation of estrogen use may reflect the fact that many uterine cancers are detected, if at all, only at necropsy. Estrogens induce bleeding as a side effect, which leads to the dilatation and curettage (D/C) that reveals these cancers. When estrogen is stopped, so is the bleeding and the use of D/C, so the cancer rates fall. The authors of the study respond that the accuracy of their data was verified, but they agree that discontinuation of estrogen use may only postpone the time of diagnosis. (12 refs)

79-4933 New Strategy in the Fight Against Cancer of the Female Genital Tract, Prompted by the Increasing Frequency of Endometrial Cancer. (Spa) de Arcos de la Plaza, M. (Seccion de Prevencion y Diagnostico Precoz del Cancer Genital Femenino, Seguridad Social, Zaragoza, Spain). *Acta Ginecol (Madr)* 33(10): 411-415; 1978.

The increasing incidence of endometrial cancer calls for the systematic cytological screening of selected high-risk groups. These include women with obesity, diabetes, hypertension, hirsutism, sterility, early menarche, late menopause, ovarian tumors, hyperplastic or polypoid lesions of the endometrium and/or endocervix, and menstrual disorders. (5 refs)

79-4934 Mind and Cancer (Letter to Editor). (Eng) Rosch, P. J. (American Inst. Stress, 124 Park Ave., Yonkers, NY 10703). *Lancet* 1(8129): 1302; 1979.

The importance of stress in the development of cancer has been suggested by the observation of an increased incidence of malignancy and of a prompt and impressive decline in immune function in persons who have lost their spouse. In addition, the patient's state of mind is important in the fight against cancer, and patients should be offered an opportunity to participate actively in their own recovery. (7 refs)

- 79-4935 Inositol Phospholipids in Membrane Function. (Eng) Michell, R. H. (Dept. Biochemistry, Univ. Birmingham, P.O. Box 363, Birmingham B15 2TT, England). *Trends Biochem Sci* 4(6): 128-131; 1979.

The role of inositol phospholipids [phosphatidylinositol (PI), phosphatidylinositol 4-phosphate, and phosphatidylinositol 4,5-bisphosphate] in membrane function is reviewed. Inositol lipids appear to be intimately involved in Ca^{2+} -mediated control of cell functions by hormones and other ligands, in cell proliferation, and in the attachment of enzymes to the plasma membrane. A PI response (stimulation of PI metabolism) can be provoked in any type of cell, provided that it possesses appropriate receptors. Many or all of the receptors that stimulate PI metabolism are similar: their action on target cells involves Ca^{2+} in some essential way, and they elevate cellular cyclic guanosine monophosphate concentrations. Activation of these receptors increases the cytosol Ca^{2+} concentration (CCC), which brings about other responses. The PI response frequently and, perhaps, universally accompanies the action of any receptor whose activation increases the CCC, and it is independent of the CCC. Fluctuations in CCC can exert appreciable control over the progression of cells through the cell cycle, with mild elevation of the CCC at appropriate times tending to accelerate proliferation. There is evidence of an increase in the rate of PI turnover in the proliferating state compared with quiescent cells of the same type; other lipids are usually unaffected. There may be a close correlation between mobilization of Ca^{2+} through the plasma membrane and an increased rate of PI turnover, without direct evidence as to whether the two events are causally related. The observation that alkaline phosphatase was released from slices of liver if they were incubated with a PI-specific phospholipase C isolated from a bacterial culture filtrate was recently confirmed. Some other plasma membrane ectoenzymes were released from liver and RBC membranes by the same treatment. PI is undoubtedly implicated in some specific and essential way in the normal attachment of these enzymes to the external surfaces of cell plasma membranes. (37 refs)

- 79-4936 Differentiation and Cancer. (Eng) Cairns, J. (Imperial Cancer Res. Fund, Mill Hill Labs., London, England). *Differentiation* 13(1): 67; 1979.

The conversion of a cell into a cancer cell can be thought of as an alteration in its state of differentiation, and mechanisms that may be involved in this process are discussed. Most human cancers arise in epithelial stem cells. These cancers are probably a change in phenotype due to a combination of mutation and altered pattern of regulation of gene expression. It seems likely that each particular class of cancer is the result of a particular alteration in the pattern of gene expression, rather than the expression of a cancer gene common to all cancers, making it unlikely that there is a universal cure for cancer. (no refs)

- 79-4937 The Significance of Cyclic AMP and Cyclic GMP in Cancer Treatment. (Eng) Tisdale, M. J. (Dept. Biochemistry, St. Thomas's Hosp. Medical Sch., London SE1 7EH, England). *Cancer Treat Rev* 6(1): 1-15; 1979.

The significance of cyclic AMP (cAMP) and cyclic GMP (cGMP) in cancer therapy is reviewed. Various chemical carcinogens and tumor promoting agents cause increases or decreases in the basal level of cAMP and alterations in the hormone responsiveness of their target tissues. Oncogenic viruses tend to cause a decrease in cAMP after transformation. A number of carcinogens have also been shown to stimulate or inhibit guanylate cyclase. Transformation tends to reduce adenylate cyclase activity; these early alterations reflected in more stable changes in enzyme activity in the resultant tumors. There are widely different levels of cyclic nucleotides in tumor cells. The apparent functional deficiency of cAMP in some tumors may be brought about by a disproportionate increase in the level of cGMP. cAMP may potentiate tumor development by inhibition of a DNA repair process. cGMP may also promote cell growth and transformation. There is evidence to indicate that cAMP can act as a tumor growth inhibitor in certain systems. In some systems, cyclic nucleotides may be involved in the regulation of tumor cell differentiation and maturation. If the activity or pattern of phosphodiesterases in neoplastic cells differs from those of normal cells, it may be possible to design drugs that will specifically inhibit the phosphodiesterase activity of only those cells and thereby increase the intracellular concentration of cAMP in cancer cells. - 79-4938 Proliferation of Hepatocytes. (Eng) Leffert, H. L. (Cell Biology Lab., Salk Inst. Biological Studies, San Diego, CA); Koch, K. S. *Ciba Found Symp* 55: 61-94; 1978.

Factors that control the proliferation of liver cells in vitro and the manner in which agents that cause liver cancer alter growth controls are reviewed. Hepatocyte proliferation may be controlled by reversible patterns of endocrine changes, monitored by the liver, involving known hormones and their receptors. A two-program model of related interactions among nutrients, specific lipoproteins, and highly phosphorylated nucleotides is postulated. This hypothesis is derived from in vitro studies of rat hepatocyte proliferation under chemically defined conditions and from in vivo studies with partially hepatectomized, hormone-infused, developing and lipotrope-deficient rats. Liver proliferative states appear to be correlated with defined patterns of endocrine changes. The physiochemical basis of these patterns is in part a set of chemical equilibria between regulatory signals and their hepatocyte receptors; the pattern itself or a subset of its elements may determine specificity. Hepatocarcinogenesis may involve altered normal responsiveness as a concomitant and/or as a cause of

REVIEW

chemically induced transformation. Promising in vitro approaches for studies of chemical hepatocarcinogenesis are outlined. (34 refs)

79-4939 The Association of Pregnancy and Breast Cancer. (Eng) Zinns, J. S. (Dept. Surgery, New York Medical Coll., Metropolitan Medical Center, New York, NY). *J Reprod Med* 22(6): 297-301; 1979.

The association of pregnancy and breast cancer (BC) is reviewed. The incidence of BC during pregnancy is rare; incidences of 3/10,000 and 10/62,000 pregnancies have been found in the literature. The av age of patients afflicted with BC while pregnant is 35-36. The quick progress of the disease during pregnancy may be due to increased hor-

monal stimulation, which causes major alterations in breast physiology. There is an increase in vascularity and lymphatic permeability. The altered immune response during pregnancy also influences the prognosis to some degree. The av delay in seeking medical attention is 11 mo for pregnant or lactating patients, in contrast to 4 mo for nonpregnant patients. The histological distribution of BC in pregnant women is similar to that in nonpregnant women. Careful and frequent examination of the breast during pregnancy is recommended. Biopsies of three dimensional lumps should be performed, and low-dose mammography with appropriate abdominal shielding is a safe diagnostic method during pregnancy. Reports indicate that there has been continued improved survival, especially for early disease. In a series of 88 patients, a 90% 5-yr survival rate was reported for those with Stage I disease. CHEMICAL CARCINOGENESIS

- 79-4940 Non-activation in the Ames Test (Letter to Editor). (Eng) Hope, J. (Environmental Safety Div., Unilever Res. Lab., Colworth House, Sharnbrook, Bedford, England). *Mutat Res* 67(2): 197-198; 1979.

The previous suggestion that in the *Salmonella typhimurium* test, a nonactivation 'control' consisting of incubation of the chemical at the highest dose level with the S9 preparation, but without the NADPH-generating system, is discussed. False negatives may be obtained when nonactivation systems that include S9 preparations are used. (no refs)

- 79-4941 In Utero Sister Chromatid Exchange Analysis for Detection of Transplacental Mutagens. (Eng) Kram, D. (Section Cellular Aging and Genetics, Lab. Cellular and Molecular Biology, Gerontology Res. Center, Natl. Inst. Aging, NIH, Baltimore, MD 21224); Bynum, G. D.; Senula, G. C.; Schneider, E. L. *Nature* 279(5713): 531; 1979.

A new approach for the detection of fetal DNA damage through the enumeration of sister-chromatid exchanges (SCE's) in mouse fetal chromosomes is described. In utero SCE analysis is relatively simple, rapid, and reproducible, and it requires small numbers of animals, allows simultaneous examination of the effect of agents on fetal and maternal cells, and may be more sensitive than previously described techniques. - 79-4942 Milky Spots (*Taches Laiteuses*) as Structures Which Trap Asbestos in Mesothelial Layers and Their Significance in the Pathogenesis of Mesothelial Neoplasia. (Eng) Kanazawa, K. (Dept. Surgery, Univ. Tsukuba Sch. Medicine, Sakura-Mura, Niihari-Gun, Ibaraki, 300-31, Japan); Roe, F. J.; Yamamoto, T. *Int J Cancer* 23(6): 858-865; 1979.

The structure and function of milky spots (*Taches laiteuses*) in the mesothelial layer of mice are described, along with the sequential changes that occur in these spots after exposure of the mice to asbestos. Crocidolite asbestos was injected sc (2 doses of 30 mg in 0.4 ml saline on 2 successive days) into the flanks of CBA/lac mice. Asbestos fibers were found in mediastinal milky spots >442 days after the injection, in the form of either naked fibers or asbestos bodies. Milky spots were the only structure in which asbestos fibers were observed in the mesothelial layer. The fact that asbestos fibers were found in the liver, spleen, kidney, and brain, in addition to the milky spots, suggests that they were transported by the bloodstream throughout the body. This assumption was confirmed by

the similar distribution of asbestos after iv administration. The vascular and cellular structure of the milky spots is such that they are particularly likely to trap blood-borne asbestos fibers. Hyperplastic changes were observed in milky spots after both sc and iv administration of asbestos. Milky spots may be involved in the genesis of mesothelial tumors in animals following their exposure to asbestos. (30 refs)

- 79-4943 Enhancement by Asbestos of Oncogenesis by Moloney Murine Sarcoma Virus in CBA Mice. (Eng) Kanazawa, K. (Dept. Surgery, Univ. Tsukuba Sch. Medicine, Sakura-Mura, Niihari-Gun, Ibaraki 300-31, Japan); Yamamoto, T.; Yuasa, Y. *Int J Cancer* 23(6): 866-874; 1979.

The enhancement of Moloney murine sarcoma virus-induced tumorigenesis by trace quantities of asbestos was studied in 3-wk-old CBA mice. Sixty-one mice were inoculated ip with 5 µg of finely ground crocidolite asbestos and 10⁵ focus-forming units of the virus. Forty-four of the mice developed palpable ip tumors, half of which died from their tumors within 100 days. The same amount of quartz and carbon similarly administered gave lower tumor incidences, 19.4% (3.2% fatal) and 11.9% (1.5% fatal), respectively. Only 1/59 mice inoculated with the virus alone developed a palpable ip tumor, and this tumor regressed spontaneously within 10 days. No tumors were encountered in mice treated with asbestos, quartz, or carbon alone. All the neoplasms had the appearance, under the light microscope, of anaplastic sarcomas. Most of them were confined to the serosal surface of the abdominal cavity, although invasion of underlying tissues was observed in some of the animals that died. Electron microscope examination of the tumors revealed the presence of C-type particles budding from the cellular surface. Some neoplastic cells showed the characteristic features of mesothelial lining cells. The role of milky spots (*Taches laiteuses*) in oncogenesis induced by asbestos and virus, especially in the induction of mesothelioma, is discussed. (35 refs)

- 79-4944 Heavy Metal (Cd, Zn, Pb, Cu, Cr) Content in Cigarette Brands Commonly Smoked in West Germany. (Ger) Muller, G. (Institut für Sedimentforschung, Universität Heidelberg, Im Neuenheimer Feld 236, D-6900 Heidelberg, W. Germany). *Chemiker-Zeitung* 103(4): 133-137; 1979.

The tobacco in 15 commercial cigarette brands commonly smoked in West Germany were analyzed for heavy metal levels by atomic absorption spectrometry. The following

minimum, mean, and maximum concentrations (in $\mu\text{g/g}$ = ppm) were found: Cd: 1.07, 1.46, 2.30; Zn: 33, 45, 64; Pb: 2.4, 3.3, 4.3; Cu: 10, 21.7, 34; Cr: 3.4, 4.9, 6.7; Fe: 292, 428, 572; Mn: 71, 133, 176. The high Cd level, which is due to uptake from emissions rather than from the soil, is emphasized with respect to a potential cocarcinogenic effect with the polycyclic aromatic hydrocarbons present in cigarette smoke. Literature data show that Cd has carcinogenic and teratogenic effects only upon parenteral administration. At an estimated transfer rate of 10%, the Cd uptake amounts to 0.08-0.37 $\mu\text{g/cigarette}$. (23 refs)

- 79-4945 Primary Biochemical Defect in Copper Metabolism in Mice with a Recessive X-Linked Mutation Analogous to Menkes' Disease in Man. (Eng) Prins, H. W. (Interuniversity Reactor Inst., Delft, Netherlands); Van den Hamer, C. J. *J Inorg Biochem* 10(1): 19-27; 1979.

Copper metabolism was studied in Brindled mice of three phenotypes: normal mice, mice with an X-linked defect comparable to Menkes' disease in man (MD mice), and heterozygous mice. ^{64}Cu or ^{67}Cu was administered ip or po. The copper concentrations were elevated in the kidneys, mucosa and muscle of the gastrointestinal tract, pancreas, and bones of the heterozygous adults compared with the normal adults; there was no significant difference in the liver concentrations. The distribution of ^{67}Cu in young heterozygous and MD mice after po administration was abnormal relative to normal mice. The kidneys of both heterozygous and MD mice irreversibly stored ^{64}Cu as a cytoplasmic protein with a mol wt of 10,000 daltons. This particular protein fraction also contained a larger amount of stable copper. There are three models that could explain the accumulation of the 10,000-dalton protein of the kidney: irreversible copper binding in an abnormal species of the protein (fraction I); a block in the copper transport from fraction I to fraction II, or an inability of copper to bind to fraction II. In the livers of both heterozygous and MD mice, more ^{64}Cu was bound in fraction II and less in fraction I than in normal mouse liver. (9 refs)

- 79-4946 On the Problems of Evaluating Bronchial Carcinoma After Exposure to Chromium Compounds. (Ger) Zober, A. (Institut für Arbeits- und Sozialmedizin und Poliklinik für Berufskrankheiten, Universität Erlangen-Nürnberg, Schillerstrasse 25-29, D-8520 Erlangen, W. Germany). *Int Arch Occup Environ Health* 43(2): 107-121; 1979.

Twenty-seven cases of lung disease due to occupational exposure to hexavalent chromium (Cr VI, 24 cases) and trivalent chromium (Cr III, 3 cases) at 7 industrial plants are reported. Lung cancer was diagnosed in 17 patients, 3

of whom had been exposed to Cr III; lung disease without carcinoma (bronchitis, emphysema, and fibrosis) was seen in 10 patients. The lung cancer was acknowledged as occupational disease in 14 cases; these 14 patients had been exposed for 2-32 yr, and the latent period (length of exposure plus delay after cessation of exposure) was 10-53 yr. The lung cancer was always preceded by emphysema or chronic bronchitis. The chromate content was analyzed in the lung tumor and in the normal lung tissue in 3 cases; the Cr content was higher in the cancer tissue than in the normal tissue in 2 cases, and it was higher in the normal tissue in 1. Histological data available for 10 cases showed squamous epithelial carcinoma in 8, dedifferentiated adenocarcinoma in 1, and small-cell carcinoma in 1; the squamous epithelial carcinoma was associated with large-cell carcinoma in 1 patient. There were no marked differences between the cancer patients and the 10 other patients with non-neoplastic lung diseases in the length of exposure and latency. (27 refs)

- 79-4947 Experimental Respiratory Carcinogenesis in Hamsters: Environmental, Physicochemical and Biological Aspects. (Eng) Stenback, F. (Univ. Nebraska Medical Center, 42nd and Dewey Ave., Omaha, NE 68105); Rowland, J. *Oncology* 36(2): 63-71; 1979.

The potential hazards associated with silicone dioxide (SiO_2), manganese dioxide (MnO_2), and agar gelatin (gel) in combination with benzo(a)pyrene (BP), dibenz(a,j)acridine (DBA), and the carrier dust Fe_2O_3 were evaluated following intratracheal administration to Syrian golden hamsters. Survival times among treated hamsters were lower than those among controls, but respiratory tract tumors developed only in animals given DBA or BP plus dust or gel. BP alone induced respiratory neoplasms in 5/46 hamsters; BP plus SiO_2 induced such tumors in 21/48 animals; and BP plus MnO_2 or 0.5% gel induced tumors in 6/46 and 6/47 animals, respectively. DBA plus Fe_2O_3 induced a respiratory neoplasm in 1/45 animals. Particle size was correlated with retention rate but not with carcinogenicity. The respiratory tumors induced by BP plus SiO_2 were preceded by proliferative dysplastic alterations not seen in animals treated with BP and MnO_2 or DBA and Fe_2O_3 . It is concluded that extensive preneoplastic changes are associated with subsequent tumor formation and are not due only to treatment with certain hydrocarbon-dust combinations. (36 refs)

- 79-4948 Histopathological Changes in Nasal Mucosa of Workers at Norwegian Nickel Refinery. (Eng) Solberg, L. A. (Dept. Pathology, Ulleval Hosp., Oslo, Norway); Torjussen, W. *Acta Otolaryngol [Suppl] (Stockh)* 360: 124; 1979.

Histopathologic changes in the nasal mucosa of 318 nickel workers at a Norwegian refinery, 15 retired nickel workers,

and 57 age-matched controls were studied. Nasal carcinoma was found in 2 nickel workers (0.6%), and epithelial dysplasia was found in 12% of the workers, 47% of the retired workers, and one control (a 65-yr-old carpenter). The data suggest that nickel compounds or factors associated with nickel refinery work may be involved in the causation of nasal carcinoma and epithelial dysplasia. (2 refs)

- 79-4949 Platinum Tetrachloride: Mutagenicity and Methylation with Methylcobalamin. (Eng) Taylor, R. T. (Biomedical Sciences Div., Lawrence Livermore Lab., Univ. California, Livermore, CA 94550); Happe, J. A.; Hanna, M. L.; Wu, R. *J Environ Sci Health [A]* 14(2): 87-109; 1979.

The methylation and mutagenicity of platinum tetrachloride (PtCl_4) for two closely related Chinese hamster ovary cell lines (CHO-S and CHO-AUXB1) were studied. Micromolar concentrations of PtCl_4 and methylcobalamin (MeB-12) reacted in water. The demethylation of MeB-12 was 90% complete after 24 hr, but the rate could be increased by catalytic amounts of K_2PtCl_6 . Pt products isolated by column chromatography included MePtCl_3^- as the principal product and $\text{MePt}(\text{H}_2\text{O})\text{Cl}_2^-$, which was identified by nuclear magnetic resonance data. In CHO-S cells, PtCl_4 induced forward mutations to the 8-azaguanine resistance/hypoxanthine-guanine phosphoribosyl transferase locus, but not to ouabain resistance. It also induced the reversion of CHO-AUXB1, a multiple auxotroph. The mutagenic effects of PtCl_4 for both cell lines were dose-dependent in the range of 5-30 μM . (18 refs)

- 79-4950 The Effect of Various Selenium Compounds in the Development of Ehrlich Ascites Tumor Cells (Meeting Abstract). (Eng) Greeder, G. (Univ. Illinois, Urbana, IL 61801); Milner, J. A. *J Nutr* 109(6): 32; 1979 (no refs)

- 79-4951 Dietary Supplementation of Stable Strontium (Meeting Abstract). (Eng) Skoryna, S. C. (St. Mary's Hosp. Centre, Montreal, Canada); Inoue, S.; Fuska, M. *J Nutr* 109(6): 33; 1979 (no refs)

- 79-4952 Potentiating Effect of Methyl Methane Sulfonate on Friend Virus Leukemogenesis In Vivo. (Eng) Raikow, R. B. (Cancer Res. Unit, Clinical Radiation Therapy Res. Center, Allegheny General Hosp., Pittsburgh, PA 15212); Meredith, R. F.; Brozovich, B. J.; Seeman, P. R.; Livingston, A. E.; Okunewick, J. P. *Proc Soc Exp Biol Med* 161(2): 210-215; 1979.

Studies were conducted to determine if methyl methanesulfonate (MMS) would act as a potentiating agent for an RNA cancer virus in vivo. MMS (2 mg ip) given 5 hr before friend leukemia virus (FLV) injection enhanced the leukemogenic action of FLV in virus-sensitive SJL/J mice and also in relatively virus-resistant B10SJF₁ mice. MMS also decreased the humoral immune response, as measured by a plaque-forming-cell assay. However, the timing of the effect of MMS on the immune system did not coincide with the timing of the MMS-related potentiation of leukemia. Hence, it is suggested that the potentiating effect of this chemical on viral leukemogenesis is more likely due to events occurring at the intracellular level rather than at the level of the humoral immune response. (35 refs)

- 79-4953 Cross Sensitivity of Mutator Strains to Physical and Chemical Mutagens. (Eng) Nasim, A. (Div. Biological Sciences, Natl. Res. Council Canada, Ottawa, Ontario K1A 0R6, Canada); Brychey, T. *Can J Genet Cytol* 21(1): 129-137; 1979.

Ten different mutator strains of *Saccharomyces cerevisiae* were tested for cross sensitivity to two alkylating agents, ethyl methanesulfonate (EMS) and methyl methanesulfonate (MMS), to determine if any were defective in the repair systems which normally deal with damage caused by these agents. For one of the mutators, strain *mut2-1*, it was shown by genetic analysis that mutator activity and MMS sensitivity are both controlled by the same gene. Two mutants, *mut2-1* and *mut7-1*, were found to be sensitive to MMS but normal in reaction to ultraviolet and γ -rays. Another group is represented by *mut1*, *mut6* and *mut8* which are not sensitive to any of the mutagens tested so far. Mutator strain *mut2-1* was also shown to be not significantly altered for levels of UV-induced forward and reverse mutations. These observations lend support to the idea of multiple repair systems that deal with DNA damage caused by different agents and also show that mutator activity can often result from the loss of normal cellular repair systems. (35 refs)

- 79-4954 Silver Sulfadiazine: Lack of Mutagenic Activity. (Eng) McCoy, E. C. (Dept. Microbiology, New York Medical Coll., Valhalla, NY 10595); Rosenkranz, H. S. *Chemotherapy* 24(2): 87-91; 1978.

Silver sulfadiazine, an antimicrobial agent, was non-mutagenic toward *Salmonella typhimurium* strains TA1535, TA1537, TA1538, and TA100 in the presence and absence of a microsomal activation mixture. In view of the relationship between mutagenicity in this system and carcinogenicity in animals, the findings suggest that the compound is also devoid of carcinogenic properties. (30 refs)

- 79-4955 Enhanced Colonic Carcinogenesis with Azoxymethane in Rats after Pancreaticobiliary Diversion to Mid Small Bowel. (Eng) Williamson, R. C. (Surgical Services, Shriners Burns Inst., Boston, MA); Bauer, F. L.; Ross, J. S.; Watkins, J. B.; Malt, R. A. *Gastroenterology* 76(6): 1386-1392; 1979.

To examine the role of biliary secretion in the differential production of chemically induced enteric neoplasia, pancreaticobiliary diversion (PBD) was performed on male Fischer rats before or after treatment with azoxymethane (AOM, 10 mg/kg/wk, sc, for 16 wk). The procedure involved diverting pancreaticobiliary secretion from the duodenum to the mid-small bowel. RNA and DNA levels in the jejunal mucosa were unchanged 30 wk after PBD. However, in the upper ileum of rats given AOM or vehicle, PBD increased the levels of both nucleic acids by 37%-102%. At 30 wk, PBD increased the RNA content of the right colon in vehicle-treated rats by 29% and the DNA content of both the right and left colon of AOM-treated rats by 30%-31%. AOM alone increased the RNA content of the jejunum and upper ileum by 31% and 17%, respectively. Neither AOM nor PBD influenced the fecal excretion of bile acids. PBD preceding AOM increased the number of tumors throughout the small bowel. Papillary or tubular adenocarcinomas (68% of the total) predominated in the duodenum and mucinous adenocarcinomas (23% of the total) predominated in the jejunum and ileum. In the large bowel, PBD increased the incidence of colonic tumors from 1.26 to 3.16 per rat ($p < 0.005$) when it preceded AOM and from 1.26 to 2.70 per rat ($p < 0.02$) when it followed AOM. Tumor frequency was greatest in the distal colon, and adenocarcinomas predominated. The incidence of metastatic adenocarcinomas increased when PBD preceded AOM. The potentiation of colonic neoplasms by PBD probably depends on the stimulation of colonic mucosal proliferation. (45 refs)

- 79-4956 The Effect of Prolonged Ethanol Intake on Some Carcinogen-activating Enzymes in Mice. (Eng) Capel, I. D. (Res. Dept., Marie Curie Memorial Foundation, The Chart, Oxted, Surrey RH8 0TL, England); Dorrel, H. M.; Jenner, M.; Pinnock, M. H.; Williams, D. C. *Biochem Pharmacol* 28(7): 1139-1141; 1979.

The effect of prolonged intake of subchronic and chronic levels of ethanol on the hepatic microsomes of male albino TO mice was investigated, along with changes in some of the parameters associated with carcinogen activation. Cytochrome P-450 and aryl hydrocarbon hydroxylase levels were increased in mice that received 1% or 10% (volume/volume) absolute ethanol in their drinking water for 24 or 32 wk. These increases corresponded to a consistent rise in microsomal protein values throughout the experiment. The binding of benzo(a)pyrene to DNA was significantly increased during 1% ethanol treatment, but it

returned to the control level after 20 wk. In mice receiving 10% ethanol, the binding of benzo(a)pyrene was consistently decreased, returning to the control level only after 32 wk. This study demonstrated that an enzyme involved in carcinogen activation can be increased as a result of the adaptation of the hepatic microsomal ethanol-oxidizing system to prolonged ethanol ingestion. (28 refs)

- 79-4957 Research Contributions: Mutagenic Activity of Ethylene Oxide, Ethylene Glycol, and 2-Chloroethanol Residues in Plastic Materials Sterilized with Ethylene Oxide. (Fre) Conan, L. (Laboratoire d'Histopathologie Certi, 59 avenue de Paris, 78000 Versailles, France); Foucault, B.; Siou, G.; Chaigneau, M.; Le Moan, G. *Ann Falsif Expert Chim* 72(773): 141-151; 1979.

The mutagenicity of ethylene oxide (EO) in aqueous solution or on ip implanted polyethylene or polyvinyl chloride sterilized with EO, of ethylene glycol (EG), and 2-chloroethanol (CE) was studied in male Swiss C.F.L.P. mice. The presence of chromosome aberrations in bone marrow cells and the percentage of polychromatic erythrocytes carrying Howell-Jolly bodies were used as indicators of mutagenicity. The quantity of EO introduced with the sterilized plastics was 0.5-5 mg/animal; the animals were sacrificed 30-50 hr after implantation. EO was also administered ip (1-200 mg/kg) and iv (100 mg/kg); EG was administered ip (1.25 and 6.25 ml/kg) and po (2.5-12.5 ml/kg); and CE was administered po (0.025-0.1 ml/kg) and ip (0.01 and 0.05 ml/kg). Untreated animals served as controls. The plastics sterilized with EO as well as CE failed to produce any signs of mutagenic activity, but EO and EG caused an increase in the percentage of erythrocytes with Howell-Jolly bodies from 0.23% in the controls to 0.13-0.47% and 0.18-0.51%, respectively. Chromosome aberrations were not seen. (23 refs)

- 79-4958 Ethanol Inhibition of Vinyl Chloride Metabolism in Isolated Rat Hepatocytes. (Eng) Hultmark, D. (Dept. Microbiology, Univ. Stockholm, S-106 91 Stockholm, Sweden); Sundh, K.; Johansson, L.; Arrhenius, E. *Chem Biol Interact* 25(1): 1-6; 1979.

Factors which could influence the metabolism of vinyl chloride (VC) by the liver were studied using hepatocytes and liver microsomes from untreated and phenobarbital (PB)-pretreated male strain R Wistar rats. VC incubated with hepatocytes was metabolized as a linear function of time. The metabolism was unaffected by PB pretreatment or metyrapone (40 μ M), but was strongly inhibited by ethanol (4 mM) and tetrahydrofuran. Dichloro-p-nitroanisole O-demethylase was strongly stimulated in the hepatocyte preparations by PB pretreatment, and the metabolism of dichloro-p-nitroanisole was partially inhibited by metyrapone, especially after PB pretreatment.

The liver microsomes showed a high capacity to convert VC to non-volatile products, this capacity being dependent on the presence of a NADPH-generating system. The microsomes were even more sensitive than the intact hepatocytes to ethanol inhibition. (20 refs)

- 79-4959 Mutagenicity of Vinyl Chloride, Vinylidene Chloride and Chloroprene in V79 Chinese Hamster Cells. (Eng) Drevon, C. (Unit Chemical Carcinogenesis, International Agency Res. Cancer, 150 cours Albert Thomas, 69372 Lyon Cedex 2, France); Kuroki, T. *Mutat Res* 67(2): 173-182; 1979.

The mutagenicity of vinyl chloride (VC), vinylidene chloride (1,1-dichloroethylene: VDC) and chloroprene (2-chloro-1,3-butadiene) was tested in V79 Chinese hamster cells in the presence of a 15,000 x g liver supernatant from phenobarbital-pretreated rats and mice. Mutations in terms of 8-azaguanine and ouabain resistance were induced in a dose-related fashion by exposure to VC vapor in the presence of the liver supernatant from phenobarbital-pretreated BDVI rats. VDC and chloroprene vapors induced a dose-related toxicity when tested with the rat liver supernatant, but these two compounds were not mutagenic in V79 cells under the assay conditions. The results are discussed with regard to the metabolic activation of the compounds and to the correlation between the carcinogenicity of VC in humans and experimental animals. (31 refs)

- 79-4960 Toxicity of Low Concentration Long-Term Exposure to an Airborne Mixture of Nitrous Oxide and Halothane. (Eng) Coate, W. B. (Hazleton Labs. America, Vienna, VA); Kapp, R. W.; Ulland, B. M. *J Environ Pathol Toxicol* 2(5, Special): 209-231; 1979.

To determine the reproductive, teratologic, cytogenetic, and tumorigenic effects of long-term exposures to escape levels of halothane + nitrous oxide, male and female Sprague-Dawley and Fischer rats were exposed to air, to 1 ppm halothane + 50 ppm N₂O, or to 10 ppm halothane + 500 ppm N₂O for 7 hr/day, 5 days/wk, for appropriate periods of time. In one experiment, young adult female rats were exposed for 60 days, then mated and reexposed from gestation day 1 or 6 to day 15. The former were permitted to deliver naturally, and the latter were delivered by C-section on day 20. The young adult males used in breeding were also exposed for 60 days prior to mating and then for a total of 52 wk thereafter. At termination, bone marrow cell and spermatogonial metaphase preparations were made and assessed for cytogenetic abnormalities. The mated females were evaluated for ovulation, pre- and postimplantation loss, fetal growth, fetal abnormalities, and early postnatal development. In a parallel experiment, 50 male and 50 female weanling rats in each group were ex-

posed for 104 wk to the same levels and then evaluated for tumor development, with emphasis on the reticuloendothelial system. There was a significant reduction in ovulation and implantation efficiency from exposure to the higher levels and a slightly retarded fetal development at both levels. No teratologic or abortifacient effects were noted. No tumorigenic effects were observed. However, cytogenetic damage to both bone marrow and spermatogonial cells was seen at both levels. (19 refs)

- 79-4961 Report on Carcinogenesis Bioassay of 1,2-Dichloroethane (EDC). (Eng) Anonymous (U.S. Dept. Health, Education, and Welfare, NCI, NIH, Bethesda, MD 20014). *Clin Toxicol* 14(2): 225-230; 1979.

The carcinogenicity of 1,2-dichloroethane (EDC, 47-299 mg/kg/day, 5 days/wk for 78 wk, po) for Osborne-Mendel rats and B6C3F1 mice was studied. In male rats, EDC caused forestomach cancers, hemangiosarcomas of multiple organs, and sc fibromas. Female rats given EDC developed mammary cancers; in some animals given the highest dose of EDC (95 mg/kg/day) these tumors appeared after as little as 20 wk. The chemical also caused breast cancers and uterine cancers in female mice and respiratory tract cancers in male and female mice. (no refs)

- 79-4962 Vinylidene Fluoride: Metabolism and Induction of Preneoplastic Hepatic Foci in Relation to Vinyl Chloride. (Eng) Stockle, G. (Institut für Toxikologie, Universität Tübingen, Wilhelmstrasse 56, D-7400 Tübingen-1, W. Germany); Laib, R. J.; Filser, J. G.; Bolt, H. M. *Toxicol Lett* 3(6): 337-342; 1979.

The tumorigenicity and metabolism of vinyl chloride (VC) and vinylidene fluoride (VF) were compared in Wistar rats. Exposure of newborn rats to VC (2,000 ppm, 8 hr/day, 5 days/wk) for 4 wk resulted in the formation of ATPase-deficient hepatocellular foci. Similar exposure to VF produced a few single foci after 10 wk. After 14 wk of exposure to VF, the number of foci was less than that observed after 4 wk of exposure to VC, and it was about one 1/100 the number found after 10 wk of exposure to VC. The rate of the metabolic conversion of VF in the rat was found to be 2 orders of magnitude lower than that of VC. The very slow metabolism of VF may explain why this compound is much weaker in eliciting preneoplastic hepatic foci in newborn rats than VC. (21 refs)

- 79-4963 Effect of DDT on Urinary Excretion of Mutagenic Metabolites of 2-Acetylaminofluorene (2-AAF) in Rats in Acute and Chronic Experiments. (Pol) Syrowatka, T. (Zakład Toksykologii Sanitarnej, Państwowy Zakład Higieny, ul. Chocimska 24, 00-791 Warsaw, Poland); Tadeusiak, B.; Ladyga, M.; Jurek, A. *Roczn. Państw. Zakł. Hig.* 30(2): 179-184; 1979.

The effect of DDT (4,4'-Dichlorodiphenyltrichloroethane) on the mutagenic activity of 2-acetylaminofluorene (AAF) metabolites excreted in the urine was studied in Wistar rats. The mutagenic activity of the urine was determined with *Salmonella typhimurium* TA 1538 with or without incubation (60 min). In the acute experiment, the animals received single doses of DDT (100 mg/kg ip) and, 24 hr later, AAF (50 mg/kg ip). In the chronic experiment, the substances were administered in the food over 35 days; the doses were 50 mg/kg of food for DDT, and 300 mg/kg of food for AAF. In both experiments, urine of AAF-treated animals showed marked mutagenic activity. DDT caused a significant reduction in the urinary level of mutagenic metabolites in both the chronic and acute experiments. (17 refs)

- 79-4964 Mutagenic Activity of Propylene Oxide in Bacterial and Mammalian Systems. (Eng) Bootman, J. (Genetic Toxicology Labs., Life Science Res., Stock, Essex, England); Lodge, D. C.; Whalley, H. E. *Mutat Res* 67(2): 101-112; 1979.

Propylene oxide (PO) was studied for its ability to induce gene mutations and primary DNA damage in bacteria and chromosomal damage in mammalian cells. The induction of base-substitution mutations was demonstrated in spot tests with *Salmonella typhimurium* and *Escherichia coli* strains at 700 µg/plate of PO; inclusion of a preparation of rat liver microsomes and cofactors (S9 mix) had no significant effect on this response. A linear dose-response relationship was recorded in plate tests with *S. typhimurium* strains TA100 and TA1535 over the range 100-750 µg/plate. When added to dividing human lymphocytes in cultures, PO caused dose-related chromosomal damage, detected at 1.85 and 9.25 µg/ml. PO administration of the compound oxide at 2 x 100, 2 x 250, or 2 x 500 mg/kg to male CD-1 mice produced no detectable increases in the incidence of micronucleated, polychromatic RBC in bone marrow. In a male mouse dominant lethal test, PO doses of 50 or 250 mg/kg/day for 14 days gave no evidence of a mutagenic action on sperm. Ip injections of PO at 2 x 300 mg/kg increased the numbers of micronucleated RBC in mice, but lower doses given by this route had no such effect. Possible reasons for the contrasting findings in vitro and in vivo are discussed. (22 refs)

- 79-4965 Inhibition of Mono-oxygenase Activities by 1,1,1-Trichloropropene 1,2-Oxide, an Inhibitor of Epoxide Hydrase, in Rat Liver Microsomes. (Eng) Shimada, T. (Osaka Prefectural Inst. Public Health, Nakamichi, Higashinari-ku, Osaka 537, Japan); Sato, R. *Biochem Pharmacol* 28(11): 1777-1781; 1979.

The addition of 1,1,1-trichloropropene 2,3-oxide (TCPO), an inhibitor of microsomal epoxide hydrase, to Sprague-Dawley rat liver microsomes caused a type I spectral

change, the magnitude of which was increased by pretreatment of the animals with phenobarbital (PB: 100 mg/kg ip), but not with 3-methylcholanthrene (25 mg/kg ip) and polychlorinated biphenyls (100 mg/kg ip). TCPO inhibited aminopyrine N-demethylation competitively and prevented covalent binding of 2,4,2',4'-tetrachlorobiphenyl to macromolecules catalyzed by liver microsomes, although it stimulated benzo(a)pyrene hydroxylation significantly. It is suggested that TCPO interacts with cytochrome P-450, especially a species of the cytochrome that is inducible by PB, and thus inhibits monooxygenase activities of liver microsomes. (32 refs)

- 79-4966 Induction of Cholera Toxin Receptors in Cultured Cells by Butyric Acid. (Eng) Fishman, P. H. (Developmental and Metabolic Neurology Branch, Natl. Inst. Neurological and Communicative Diseases, NIH, Bethesda, MD 20205); Atikkan, E. E. *J Biol Chem* 254(11): 4342-4344; 1979.

Exposure of HeLa cells to sodium butyrate caused an increase in cholera toxin receptors as measured by increased binding of ¹²⁵I-cholera toxin to the intact cells. The process was dependent on time and butyrate concentration; maximal increases (over 40-fold) were observed at 48 hr and 5 mM sodium butyrate. Other short chain fatty acids were less effective in elevating cholera toxin receptors in the order: butyrate > pentanoate >> hexanoate > propionate. Acetate and isobutyrate had no effect. The increase in toxin receptors caused by butyrate was reversible and occurred in serum-free medium. The affinity of cholera toxin for control and butyrate-treated HeLa cells appeared to be similar. Butyrate also induced an elevation in cholera toxin receptors in rat C6 glial and Friend erythroleukemic cells but not in a butyrate-resistant HeLa mutant. The increase observed in Friend cells paralleled the increase in ganglioside GM1 (galactosylglucosylceramide), the reported cholera toxin receptor. Although no GM1 could be detected in untreated HeLa cells, small amounts were found in cells exposed to butyrate. (19 refs)

- 79-4967 In Vitro Transformation of Lung Cells of Young Hamsters by Chloro-2-butadiene. (Fre) Menezes, S. (Section de Biologie, Institut Curie, 26, rue d'Ulm, 75231 Paris Cedex 05, France); Papadopoulos, D.; Levy, S.; Markovits, P. *C R Acad Sci [D] (Paris)* 288(10): 923-926; 1979.

The carcinogenicity of 2-chlorobutadiene (CB, 1-500 µg/ml) was studied in vitro in normal hamster lung cell cultures. The carcinogenicity was determined from the take rate after intraocular transplantation of cells. While only 1 spontaneous tumor was found after the 33rd passage of untreated control cells, the take rates found after 5 and 13-14 passages of cells treated with 1 µg/ml concentration were

2/3 and 9/10, respectively. Further increase in the concentration did not increase the take rate. The tumors (fibrosarcomas, some of them showing signs of high malignancy) developed 17-62 days after grafting 10^3 - 10^5 cells. (5 refs)

79-4968 Reaction of Cyclohexane Oxides with Phosphodiester - Towards Understanding the Reaction of Benzo[a]pyrene Diol Epoxide with DNA. (Eng) Chan, T. H. (Dept. Chemistry, McGill Univ., Montreal, Quebec, Canada); DiRaddo, P. *Tetrahedron Lett* (22): 1947-1950; 1979.

The reaction of cyclohexene oxides (CO) with dialkyl and diaryl hydrogen phosphates (HP) was studied as a model for the reaction of benzo(a)pyrene (BP) diol epoxide with nucleic acids. CO reacted with a number of HP to give in good yield esters of *trans*-2'-hydroxycyclohexyl phosphate. CO also reacted with anilinium diphenyl phosphate in benzene to give an epoxide with a *trans*-opening. When phosphodiester were reacted with *cis*- and *trans*-cyclohexanol 2,3-oxide, the opening of the epoxides in all cases was a stereospecific *trans*-opening. The reaction was also regiospecific, with the phosphate attacking the 3' position. It is concluded that phosphodiester can be converted efficiently to phosphotriesters by CO and that the same conversion can be achieved with amine salts of the phosphates. Thus reaction of BP diol epoxide with nucleic acids is chemically feasible. Under acidic conditions, the presence of a neighboring hydroxy group appears to be sufficient to confer regiospecificity on the attack of the phosphate on the epoxide in an S(N)2 mechanism. (11 refs)

79-4969 Induction of Rat Liver Microsomal Enzymes by Cycloheximide. (Eng) Devasagayam, T. P. (Biology and Agriculture Div., Bhabha Atomic Res. Centre, Bombay 400 085, India); Pushpendran, C. K.; Eapen, J. *Biochem Pharmacol* 28(11): 1731-1734; 1979.

The effects of cycloheximide (2 mg/kg ip) on hepatic microsomal enzymes of female Wistar rats were studied. NADPH cytochrome c reductase of smooth microsomes and glucose-6-phosphatase of rough and smooth microsomes attained peak activities 2 hr after cycloheximide treatment. Cytochrome P-450 and cytochrome b₅ levels in the rough microsomes were highest 6 hr postinjection. On the other hand, the compound reduced ATPase activity in the smooth microsomes. All the components studied, except NADPH cytochrome c reductase of the smooth microsomes, approached control values 24 hr after the treatment. The rough and smooth microsomes differed in their responses to cycloheximide. The ATPase activity of the smooth microsomes declined more than that of the rough microsomes, whereas the levels of the mixed-function oxidases were generally higher in the smooth

microsomes. In addition, the decline in NADP cytochrome c reductase activity of the smooth microsomes was followed by a second increase in enzyme activity, with the result that enzyme levels were twofold higher than normal at 24 hr. (33 refs)

79-4970 Oxidative Deamination of Cyclohexylamine and Its Homologs by Rabbit Liver Microsomes. (Eng) Kurebayashi, H. (Dept. Medical Chemistry, National Inst. Hygienic Sciences, Kamiyoga, Setagaya, Tokyo, Japan); Tanaka, A.; Yamaha, T. *Biochem Pharmacol* 28(11): 1719-1726; 1979.

Cyclohexylamine (CHA) and its homologs cyclopentylamine (CPA) and cycloheptylamine (CHPA), which formed type II spectral changes in hepatic microsomes, were deaminated to the corresponding ketones by rabbit liver microsomes in the presence of NADPH and molecular oxygen. The alicyclic ketones were then reduced to the alcohols, in which the av percentages in the deaminated products were approx 75% CHA, 3% CPA, and 14% CHPA. The apparent Km's for these amines were 5.0 mM for CHA, 4.2 mM for CPA and 2.1 mM for CHPA; Vmax's were 11.0 (CHA), 42.1 (CPA) and 16.4 (CHPA) nmoles/mg protein/30 min. The deamination of these alicyclic primary amines was dependent on both NADPH and oxygen, and it was inhibited by carbon monoxide, SKF 525A, metyrapone, potassium cyanide, and mercuric chloride. These experiments indicate that the deamination of the alicyclic primary amines is catalyzed by a microsomal cytochrome P-450-dependent monooxygenase system in the rabbit liver. Cyclohexanone oxime and other oximes that were also identified in the incubation mixture may be intermediates of the microsomal deamination of alicyclic primary amines. (27 refs)

79-4971 Induction of Sister-chromatid Exchanges in Cultured Human Cells by an Organophosphorus Insecticide: Malathion. (Eng) Nicholas, A. H. (Center Human Genetics, Univ. Leuven, Minderbroedersstraat 12, B-3000 Leuven, Belgium); Vienne, M.; Van Den Berghe, H. *Mutat Res* 67(2): 167-172; 1979.

Because malathion is a widely used organophosphorous insecticide, the effects of nontoxic concentrations (2.5-40 µg/ml) on sister-chromatid exchange (SCE) frequencies were determined. Human fetal fibroblasts were exposed once or twice to malathion, with 20 hr between exposures. A single exposure to 40 µg/ml malathion resulted in a highly significant increase in the number of SCE's. After a double exposure, 20 µg/ml malathion induced an even greater increase in SCE frequencies. Comparison of these frequencies after single and double exposures indicated a cumulative effect; the number of SCE's at 5 µg/ml or

higher was significantly greater after the double exposure. An analysis of SCE's by chromosome group showed that exchanges were distributed approx according to chromosome length. (24 refs)

- 79-4972 Evaluation of Bravo, Phosdrin and Telvar as Possible Environmental Mutagens. (Eng) Kahlon, P. S. (Tennessee State Univ., Nashville, TN 37203); Banerjee, M. R. *Bull Environ Contam Toxicol* 22(3): 365-370; 1979.

The mutagenicities of three pesticides (Bravo, mevinphos, and monuron) for barley shoot tips (*Hordeum vulgare* cv. Trent) were studied. Bravo (250-1000 ppm) did not significantly increase chromosome aberrations, dicentric bridges, or multipolar anaphases and caused essentially no seedling injury as measured by growth. Mevinphos (250-1000 ppm) significantly increased chromosomal aberrations ($P < 0.01$), caused a high frequency of multipolar and polypoid anaphases, and caused 33%-40% seedling injury. It did not significantly increase dicentric bridges. Monuron (500-1000 ppm) significantly increased chromosome aberrations ($P < 0.01$), increased the frequency of dicentric bridges, and caused 17.2% (250 ppm) to 25.9% (500 ppm) seedling injury. (12 refs)

- 79-4973 Regenerative Proliferation of Mouse Epidermal Cells Following Application of a Skin Irritant (Cantharidin). Flow Microfluorometric DNA Measurements and [3 H]TdR Incorporation Studies of Isolated Basal Cells. (Eng) Clausen, O. P. (Inst. Forensic Medicine, Rikshospitalet, Oslo 1, Norway). *Cell Tissue Kinet* 12(2): 135-144; 1979.

Cantharidin (CTD), a strong skin irritant and a weak skin carcinogen, was applied in benzene soln to the backs of hairless mice (hr/hr Oslo strain). Single cell suspensions of epidermal basal cells were obtained and flow microfluorometric measurements of cellular DNA content were made. Smears were taken for autoradiography studies, and the [3 H]thymidine labeling index (LI) and mean grain count (MGC) were assessed up to 3 days after CTD application. Three successive peaks of cells with S-phase DNA content accompanied by three LI peaks were observed. The first two peaks were followed by peaks of cells in the G_2 phase, indicating that after the acute cell injury caused by CTD the cells traversed the cell cycle in partial synchrony through two subsequent cell cycles, each of 10-12 hr duration. During this phase of rapid proliferation, the LI reached the proportion of cells in the S-phase, contrary to what is observed in untreated mouse epidermis, where the labeled cells contribute to about half the proportion of cells with S-phase DNA content. The first two peaks of cells in the S phase and the LI coincided with an increased MGC, whereas the third peak was accompanied by a

MGC significantly below control values. This indicates that the latter peak is due to a longer DNA synthesis time rather than to a partially synchronized and increased cell proliferation. The duration of the G_1 , S, and G_2 phases seems to be reduced initially in rapidly proliferating epidermis. (32 refs)

- 79-4974 Redox Potential-dependent Nitrite Metabolism by *Salmonella typhimurium*. (Eng) Page, G. V. (Dept. Food Science, Cook College, Rutgers, The State Univ., New Brunswick, NJ 08903); Solberg, M. *Appl Environ Microbiol* 37(6): 1152-1156; 1979.

Studies demonstrating that *Salmonella typhimurium* is capable of metabolizing sodium nitrite are presented. Metabolism may take place by means of a nitrite-reducing enzyme function which is redox controlled. (24 refs)

- 79-4975 Sodium Nitrite and Sorbic Acid Effects on *Clostridium botulinum* Spore Germination and Total Microbial Growth in Chicken Frankfurter Emulsions During Temperature Abuse. (Eng) Sofos, J. N. (Dept. Food Science and Nutrition, Univ. Minnesota, St. Paul, MN 55108); Busta, F. F.; Allen, C. E. *Appl Environ Microbiol* 37(6): 1103-1109; 1979.

Clostridium botulinum spore germination occurred within 3 days following inoculation in both control and nitrite-treated mechanically deboned chicken meat frankfurter-type emulsions. Sorbic acid alone or in combination with nitrite significantly inhibited spore germination. A much longer incubation period was necessary for toxin formation in nitrite-sorbic acid combination treatments as compared with controls or nitrite and sorbic acid used individually. Total growth was unaffected by nitrite, whereas sorbic acid appeared to depress it. (24 refs)

- 79-4976 Subchronic Inhalation Toxicity of Nitromethane and 2-Nitropropane. (Eng) Lewis, T. R. (Natl. Inst. Occupational Safety and Health, Cincinnati, OH 45226); Ulrich, C. E.; Busey, W. M. *J Environ Pathol Toxicol* 2(5, Special): 233-249; 1979.

The subchronic inhalation toxicity of Nitromethane (NM) and 2-nitropropane (2-NP), two widely used industrial chemicals, was determined in order to recommend acceptable exposure levels in the workplace. Fifty male rats and 15 male rabbits were exposed to 98 or 745 ppm of NM or to 27 or 207 ppm of 2-NP 7 hr/day, 5 days/wk, for periods up to 24 wk. Fifty rats and 15 rabbits were exposed to filtered air for similar lengths of time, and they served as controls. Ten rats and five rabbits from each exposure and control

group were sacrificed at various times ranging from 2 days to 6 mo postexposure. Effects relatable to exposure to NM were a decreased body wt gain in rats following 8 wk of exposure to 745 ppm and a thyroid effect evidenced by an increased thyroid wt and decreased serum thyroxin levels. The latter was most notable in rabbits. Liver wts were significantly elevated in rats exposed to 207 ppm of 2-NP for 1, 3, and 6 mo. No exposure-related gross or microscopic alterations were seen in any of the tissues examined for rats and rabbits exposed to 98 or 745 ppm of NM and 27 ppm of 2-NP or in tissues of rabbits exposed to 207 ppm of 2-NP. Multiple hepatocellular carcinomas and numerous neoplastic nodules were seen in all 10 rats killed following 6 mo of exposure to 207 ppm of 2-NP, indicating that 2-NP is a potent carcinogen in the rat. (7 refs)

79-4977 Oral Chenodeoxycholic Acid Therapy and Colorectal Carcinoma: An Experimental Study. (Ger) Sauer, H. D. (Abteilung für Allgemeinchirurgie, Chirurgische Universitätsklinik, Martinstr. 52, D-2000 Hamburg 20, W. Germany); de Heer, K.; Mitschke, H. *Z Gastroenterol* 17(4): 236-243; 1979.

The effect of treatment with chenodeoxycholic acid (CDCA) on the carcinogenic activity of 1,2-dimethylhydrazine (DMH) was studied in young male Wistar rats. Twenty rats (Group 1) were treated with DMH (20 mg/kg/wk sc for 8 wk). Twenty other rats (Group 2) were treated with DMH in the same manner and also with CDCA (330 mg/100 g of diet, corresponding to 75 ± 25 mg po) during the same time. Twenty other animals (Group 3) were treated with CDCA only. All animals were sacrificed and examined 10 wk after the last DMH injection. The tumor frequency was 1/20 in Group 1 (adenoma), 3/20 (all carcinomas) in Group 2, and 0/20 in Group 3. All tumors were located in the descending colon. The findings indicate that the incidence of DMH-induced tumors following the simultaneous administration of CDCA is significantly increased and that patients treated with CDCA for radiolucent gallstones should be registered and followed up in order to gain definite information on its possible role as tumor promoter. (45 refs)

79-4978 Histopathological Studies on Experimentally Induced Pulmonary, Pleural and Peritoneal Neoplasms in Mice by Intraperitoneal Injection of Chrysotile Asbestos and N-Methyl-N-nitrosourea. (Eng) Kawai, T. (Dept. Pathology, Keio Univ. Sch. Medicine, 35 Shinanomachi, Shinjuku-ku, Tokyo 160, Japan). *Acta Pathol Jpn* 29(3): 421-433; 1979.

The cocarcinogenic effects of asbestos were studied following the administration of chrysotile asbestos (2.7 mg ip every 2 wk) and/or N-methyl-N-nitrosourea (MNU, 0.2 mg ip once weekly) for 22 wk to female dd mice. Multiple pulmonary adenomas (PA's) developed in 16/20 mice

given MNU alone, and 1 mouse developed a gastric leiomyosarcoma, 1 developed an intestinal fibrosarcoma, and 2 developed uterine carcinomas. In mice given chrysotile alone, cellular nodules developed on the serosa. A pleural tumor developed in one mouse and peritoneal tumors developed in two; neither asbestos fibers nor bodies were present in the pleural tumor. In mice given MNU plus chrysotile, 6/20 developed pulmonary carcinomas and 4/20 developed peritoneal tumors. The number of carcinomas/animal was greater and the latency time to tumor induction was smaller in this group than in the other two. This suggests that the chrysotile had a promoting or cocarcinogenic effect. A peritoneal tumor from the MNU plus chrysotile group was serially transplanted through nine passages in athymic nude mice. The original tumor and the transplanted tumors were all sarcomas of possible myogenic origin. (32 refs)

79-4979 Survival of Cells Implanted in the Embryonic Chick Limb Bud: A Difference Between Normal and Malignant Rat Brain Cells. (Eng) Tickle, C. (Dept. Biology as Applied to Medicine, Middlesex Hosp. Medical Sch., Cleveland St., London W1P 6DB, England); Crawley, A.; Roscoe, J. P. *J Cell Sci* 37: 143-156; 1979.

The fate of normal and malignant rat brain cells implanted in the embryonic chick limb bud was followed. Cells from normal rat brain tissue did not survive, and few cells could be found 1 day after grafting. In contrast, cells from a glioma and cells from a rat brain cultured 112 days after transplacental exposure to ethylnitrosourea survived well, and many mitoses were observed. These malignant cells also invaded the limb. The behavior of normal and malignant cells was followed at shorter times after grafting, and some invasion by the normal cells was detected. The first signs of normal cell degeneration were apparent around 7 hr after grafting, and after this the grafts progressively deteriorated. These results support the idea that the ability of cells to survive and grow in embryonic tissues is a characteristic of malignant cells. (32 refs)

79-4980 The Fine Structure of Stratified Ependyma in the Ventricular Wall of N-Ethyl-N-nitrosourea-treated Rats. (Eng) Pilkington, G. J. (Dept. Neurological Studies, Middlesex Hosp. Medical Sch., London W1P 8AA, England); Lantos, P. L. *Acta Neuropathol (Berl)* 46(3): 173-176; 1979.

Abnormal features in the ependymal lining of BD-IX rats treated transplacentally with N-ethyl-N-nitrosourea (ENU: 30 mg/kg, ip, on gestation day 15) were studied. Abnormal cell clusters and microtumors were found in and around the subependymal plate region from 8 wk of age onward. In one case, a tumor showing predominantly ependymal differentiation was observed. The ependymal cells at the inferior aspect of the lateral ventricles of 3/40 ENU-treated

rats formed a stratified lining composed of layers of well-differentiated ependymal cells up to 15 cells thick. In addition, there were ectopic ependymal cells dispersed haphazardly in the underlying neuropile. Occasionally, ectopic ependymal cells formed channels or cavities into which cilia and microvilluslike processes projected from the constituent cells. The cells showed no morphological signs of neoplastic transformation. None of the observed abnormalities were observed in untreated control rats. (10 refs)

- 79-4981 Prenatal Induction of Hepatocellular Glycogen Storage Areas and Tumors in Mice by Ethylnitrosourea. (Ger) Bannasch, P. (Abteilung für Cytopathologie, Deutsches Krebsforschungszentrum, Im Neuenheimer Feld 280, D-6900 Heidelberg, W. Germany); Mayer, D.; Venske, G. *Virchows Arch [Cell Pathol]* 30(2): 143-160; 1979.

Thirty-five C57/Bl₆ mice received a single dose of ethylnitrosourea (60 mg/kg ip) on day 16 of pregnancy. The livers of 65 male and 69 female offspring of the treated animals and of 63 male and 68 female offspring of untreated control mice were investigated for glycogen storage and neoplastic changes at different ages from 5 to 78 wk. In the experimental animals glycogen storage areas were found in 1/13 males and 0/13 females sacrificed at the age of 5 wk; in 0/4 males and 0/6 females at the age of 10 wk, in 3/13 males and 5/16 females at the age of 15-20 wk, in 9/9 males and 4/6 females at the age of 26 wk, in 5/22 males and 5/17 females at the age of 52 wk, and in 0/4 males and 0/11 females at the age of 78 wk. Glycogen-rich neoplastic nodules were found in experimental animals in 0/13 males and females each at the age of 5 wk, in 0/4 males and 0/6 females at the age of 10 wk, in 1/13 males and 0/16 females at the age of 15-20 wk, in 3/9 males and 0/6 females at the age of 26 wk, in 14/22 males and 7/17 females at the age of 52 wk, and in 2/4 males and 3/11 females at the age of 78 wk. Otherwise, no significant differences were found in the hepatic glycogen content between the experimental and control animals in the age bracket 15-20 wk. The first hepatocellular carcinomas were found at the age of 52 wk in both experimental males (15/22) and females (2/17). At the age of 78 wk, carcinomas were found in 4/4 males and 5/11 females. At the age of 26 wk, the hepatic glycogen content was significantly higher in the male experimental animals than in the male controls. The accumulated glycogen was found predominantly in the cytoplasmic matrix, sometimes in close contact with membranes of the agranular endoplasmic reticulum. Many cells of the neoplastic nodules contained liposomes and large spongy bodies in the dilated cisternae of the granular endoplasmic reticulum. Only 1 neoplastic nodule was seen in the controls. The findings indicate a close relationship between the development of prenatally induced hepatocellular tumors and focal hepatic glycogenosis in mice. (43 refs)

- 79-4982 Tumor Development in Lung of ddY Mice Following Transplacental Exposure to 1-Ethyl-1-nitrosourea. (Eng) Umezawa, I. (Kitasato Inst., Shirokane 5-9-1, Minato-ku, Tokyo 108, Japan); Komiyama, K.; Kawakubo, Y.; Nishiyama, Y.; Hata, T. *Gann* 70(3): 379-382; 1979.

A method for inducing lung tumors with 1-ethyl-1-nitrosourea (ENU) in 100% of experimental animals at almost the same time and within a short period was developed. Pregnant ddY mice were given a single ip injection of 58.5 mg/kg ENU between gestation days 13 and 19. Within 4-6 wk after birth, pulmonary tumor nodules were found in all offspring exposed to ENU. Histologically, they were found to be adenomas. The number of tumor nodules could be counted under the stereomicroscope starting around day 40 after birth. The size of the tumors increased with time, but the number of tumor nodules did not increase markedly. Weekly injections of urethan (0.5 mg/g ip, 0-3 wk after birth) or ENU (0.05 mg/g iv, 3-6 wk after birth) into mice pretreated with ENU during the fetal stage enhanced the number of pulmonary adenomas. The only other tumors that developed were a few lymphomas. Tumor development in the lung by injection of ENU in ddY mice during gestation is reproducible, relatively simple, and rapid. This method may be useful for the screening of antitumor agents. (13 refs)

- 79-4983 Comparison of Response of Fischer-344 and Charles River Rats to 1.5% Nitrilotriacetic Acid and 2% Trisodium Nitrilotriacetate, Monohydrate. (Eng) Anderson, R. L. (Miami Valley Lab., Procter & Gamble Co., Cincinnati, OH 45247); Kanerva, R. L. *Food Cosmet Toxicol* 17(2): 137-140; 1979.

The response of Charles River and Fischer-344 rats to dietary 1.5% nitrilotriacetic acid (NTA) and 2% trisodium nitrilotriacetate, monohydrate ($\text{Na}_3\text{NTA}\cdot\text{H}_2\text{O}$) were compared in a 4-wk feeding study. The Charles River rats consumed more NTA ($\mu\text{mol/kg}$ body wt/day) than the Fischer-344 rats. In spite of the different ingestion rates, the two strains gave similar qualitative responses to NTA. The ingestion of NTA was associated with reduced growth, increased kidney/body wt ratio, increased urinary Ca, hematuria, and the presence of crystalline CaNaNTA in the urine. These findings also applied to $\text{Na}_3\text{NTA}\cdot\text{H}_2\text{O}$; however, the incidence of hydronephrosis induced by this compound was greater in Charles River rats than in Fischer rats. - 79-4984 1-Naphthylthiourea: A Mutagenic Rodenticide That Transforms Hamster Embryo Cells. (Eng) Kawalek, J. C. (Chemical Carcinogenesis Program, NCI Frederick Cancer Res. Center, Frederick, MD 21701); Andrews, A. W.; Pienta, R. J. *Mol Pharmacol* 15(3): 678-684; 1979.

The mutagenicity of 1-naphthylthiourea (1-NTU) for *Salmonella typhimurium* strain TA 1538 and its ability to transform hamster embryo cells (HEC) were studied. 1-NTU was mutagenic when metabolized by liver microsomes from male Sprague-Dawley rats pretreated with Aroclor-1254 or phenobarbital. Two major fractions were separated by thin-layer chromatography (TLC): fraction A, which was not characterized, was only weakly mutagenic; and fraction B, which resembled 1-NTU, was as mutagenic without metabolic activation. At 1.0-25 $\mu\text{g}/\text{ml}$, 1-NTU also transformed HEC, but the individual TLC fractions transformed only at high concentrations. None of several other thiourea derivatives were mutagenic for *S. typhimurium* strains TA 1535 and TA 1538. Negative results were also obtained under conditions where a 1% level of contamination by 2-naphthylamine would have been detected. (23 refs)

79-4985 Interaction of Small Molecules with Phospholipid Bilayers. Binding to Egg Phosphatidylcholine of Some Uncharged Molecules (2-Acetylaminofluorene, 4-Dimethylaminoazobenzene, Estrone and Testosterone) That Bind to Ligandin and Aminoazo-Dye-binding Protein A. (Eng) Tipping, E. (Freshwater Biological Assoc., Ferry House, Ambleside, Cumbria LA22 0LP, England); Ketterer, B.; Christodoulides, L. *Biochem J* 180(2): 319-326; 1979.

The possible involvement of ligandin and aminoazo dye-binding protein A in intracellular transport was assessed by determining how their ligands, most of which are molecules with hydrophobic moieties, interact with cellular membranes. To obtain this information, the interactions of 2-acetylaminofluorene (AAF), 4-dimethylaminoazobenzene (DAB), estrone, and testosterone with aqueous dispersions of egg phosphatidylcholine and egg phosphatidylcholine/cholesterol (1:1 molar ratio) were examined by equilibrium dialysis and spectrophotometry. At 25 C and pH 7.4, the partition coefficients for binding to phosphatidylcholine [expressed as (mol of ligand bound/mol phosphatidylcholine)/unbound ligand concentration] were 5.0×10^3 , 2.1×10^4 , 3.1×10^3 , and 4.2×10^2 liters $\cdot\text{mol}^{-1}$ for AAF, DAB, estrone, and testosterone, respectively. In the ranges studied, these values were independent of concentration. The introduction of cholesterol into the lipid bilayers caused large decreases in the partition coefficients of estrone and testosterone, but had relatively little effect on the binding of AAF and DAB. By assuming that the interactions with egg phosphatidylcholine bilayers resemble those with the phospholipid components of mammalian intracellular membranes, the phosphatidylcholine partition coefficients, together with data for binding to the intracellular proteins ligandin and aminoazo dye-binding protein A, enable the subcellular distributions of the four components to be estimated. For the rat hepatocyte, up to 98%, 99%, 89%, and 58% of the total AAF, DAB, estrone and testosterone may be membrane-bound, respectively. (34 refs)

79-4986 Inhibition of RNA Synthesis by Derivatives of the Carcinogen 2-Acetylaminofluorene. (Eng) Austin, G. E. (Dept. Pathology, UCLA Sch. Medicine, Los Angeles, CA 90024); Moyer, G. H. *Proc Soc Exp Biol Med* 161(2): 220-224; 1979.

The mechanism by which N-hydroxy-N-2-acetylaminofluorene inhibits rat hepatic RNA synthesis was studied using the reactive ester N-acetoxy-N-2-acetylaminofluorene (N-acetoxy-AAF). Preincubation of isolated Sprague-Dawley rat nuclei with N-acetoxy-AAF (10^{-4} - 10^{-3} M) inhibited the ability of the nuclei to carry out RNA synthesis using an endogenous template or the exogenous template poly d(AT). Likewise, the template ability of DNA for RNA synthesis and the transcriptional capacity of RNA polymerases I and II were inhibited by preincubation of these macromolecules in vitro with N-acetoxy-AAF. Inactivation of enzyme or template by N-acetoxy-AAF was associated with and presumably caused by binding of AAF derivatives to these macromolecules. AAF binding required to inactivate polymerase or DNA in vitro was greater than that observed in vivo under conditions in which RNA synthesis was inhibited to a comparable extent, suggesting that additional mechanisms may operate in vivo to sensitize enzyme and template to inactivation by AAF binding. (18 refs)

79-4987 Application of ^{13}C and ^{15}N Spectroscopy to the Study of Electronic Delocalization in N-N Bonds: Nitrosamines, Hydrazones, Triazines and Related Protonated Species. (Eng) Gouesnard, J. P. (Chimie Organique Physique, ERA 312 CNRS, 2, rue de la Houssiniere, 44072 Nantes, France); Martin, G. J. *Org Magn Reson* 12(5): 263-270; 1979.

^{13}C and ^{15}N spectroscopy was used to study nitrogen lone-pair delocalization in N-N containing compounds: nitrosamines, nitramines, hydrazines, hydrazones, and triazines. Structure-chemical shift correlations were derived for nitrosamines, and equations were computed that permit the prediction of the electronic delocalization, expressed in terms of free enthalpy of activation. ^{15}N spectroscopy was also used to study the protonated species of nitrosamines and acceptor-donor complexes of nitrosamines with Lewis acids. (42 refs)

79-4988 Evaluation of Three Metabolic Activation Systems by a Forward Mutation Assay in *Salmonella*. (Eng) Pueyo, C. (Catedra de Genetica, Escuela Tecnica Superior de Ingenieros Agronomos de Cordoba, Cordoba, Spain); Frezza, D.; Smith, B. *Mutat Res* 64(3): 183-194; 1979.

Three mutagenicity assays, the intrasanguineous host-mediated assay (1), the microsomal assay in vitro (2), and

the isolated organ-mediated assay (3), were evaluated with the use of *Salmonella typhimurium araD531* strain SV3 as the indicator microorganism and dimethylnitrosamine (DMN) as the test substance. Forward mutations to L-arabinose resistance were selected in all assays. When SV3 was injected iv into male CD₁ mice, it disappeared rapidly from the bloodstream and was recovered mainly from the liver and, in smaller quantities, from the lungs and kidneys. No bactericidal action was found for up to 240 min of incubation. In assay 2, mutation induction was measured in bacteria recovered from the liver, lungs, and kidneys of CD₁ mice and CD rats treated with DMN (50-58 mg/kg via a metal cannula into the stomach). The frequency of forward mutations increased dramatically in these tissues. Liver bacteria had the highest mutation frequencies in most cases. The response was highest in the organs of female mice, followed by those in male mice and male rats. In comparison, assay 2 was relatively inefficient. Positive effects were restricted to mouse liver or kidney and rat liver microsomal preparations, and they did not surpass in vivo values, even with a 65-fold higher DMN concentration. In assay 3, bacteria recovered from rat liver perfused with 50 mM DMN showed an increased frequency (per 10⁶ cells) of 3,121 mutants, vs a control value of 10.6 mutants. In contrast, bacteria from the liver perfusate showed a mutation frequency of only 43 mutants. Bacteria recovered from rat lungs perfused with DMN showed a slight increase in mutation frequency that was only slightly above the value for the lung perfusate (43 and 10, respectively). The high sensitivity of assay 1 makes it useful for screening environmental mutagens. (33 refs)

- 79-4989 The Effect of Ammonium Sulfate on the Metabolism of Dimethylnitrosamine and Other Xenobiotics by Rat Hepatic Microsomes. (Eng) Lake, B. G. (British Industrial Biological Res. Assoc., Woodmansterne Rd., Carshalton, Surrey, SM5 4DS, England); Phillips, J. C.; Harris, R. A.; Gangolli, S. D. *Drug Metab Dispos* 7(3): 181-187; 1979.

The addition of 125-1,000 mM (NH₄)₂SO₄ to rat hepatic washed microsomal preparations markedly stimulated the rate of in vitro metabolism of the hepatocarcinogen dimethylnitrosamine. Solute treatment also stimulated the activities of NADPH-cytochrome c reductase, NADPH oxidase, the N-oxidation of N,N-dimethylaniline, and the fluorescent interaction of 8-anilino-1-naphthalenesulfonic acid (ANS) with hepatic microsomes. (NH₄)₂SO₄ had a varied effect on the activities of a number of mixed-function oxidase (MFO) enzyme activities. Whereas the activities of aniline 4-hydroxylase and 4-nitrobenzoic acid nitroreductase were enhanced at all solute concentrations, several other MFO enzyme activities were either progressively inhibited or stimulated at low and inhibited at high (NH₄)₂SO₄ concentrations. Solute treatment had no effect on microsomal cytochrome P-450 content but inhibited the activities of glucose 6-phosphatase and uridine

diphosphate-glucuronyltransferase. All of the observed changes in enzyme activities and ANS-microsome fluorescence interaction were found to be reversible when the solute was removed by centrifugation. These findings suggest that (NH₄)₂SO₄ and certain other solutes can reversibly modify the conformation of microsomal membranes in such a manner as to affect microsomal enzyme activities. (52 refs)

- 79-4990 Influences of Inducers and Inhibitors of the Microsomal Monooxygenase System on the Alkylating Intensity of Dimethylnitrosamine in Mice. (Eng) Appel, K. E. (Abt. Molekulare Toxikologie, Institut für Biochemie, Deutsches Krebsforschungszentrum, Im Neuenheimer Feld 280, D-6900 Heidelberg, W. Germany); Schwarz, M.; Rickart, R.; Kunz, W. *J Cancer Res Clin Oncol* 94(1): 47-61; 1979.

The effects of inducers [phenobarbital (PB) and 3-methylcholanthrene (3-MC)] and inhibitors (SKF 525A and CFT 1201) of the microsomal monooxygenase system on the alkylating capacity of ¹⁴C-diethylnitrosamine (¹⁴C-DEN, 10 mg/kg, ip) were studied in male NMRI mice. ¹⁴C-labeling of RNA and DNA was increased in mice pretreated with SKF 525A or CFT 1201 and decreased in mice treated with PB or 3-MC. Labeling of proteins was increased after pretreatment with any of the agents. Enhancement or reduction of specific activity occurred in all macromolecules to approx the same extent; no preferential alkylation of a particular cellular compartment was detected. In addition, no evident differences in the specific activities of the nucleic acids representing different cell compartments were detected. At the max alkylation time (approx 5 hr after DMN administration), incorporation of label into adenine and guanine was found in ribosomal RNA but not DNA. 1-Methyladenine could not be detected in DNA. It appeared that the changes in ¹⁴C activity were due to alterations in alkylating intensity and not to incorporation of labeled C₁-fragments. (41 refs)

- 79-4991 Comparative Studies of Neoplastic Response to a Single Dose of Nitroso Compounds. 6. The Effect of Diethylnitrosamine in Syrian Golden Hamsters. (Eng) Ii, Y. (Eppley Inst. Res. Cancer, Univ. Nebraska Medical Center, 42nd and Dewey Ave., Omaha, NE 68105); Pour, P.; Althoff, J. *J Cancer Res Clin Oncol* 94(1): 1-5; 1979.

The relationship between the effect of a single sc injection of different DEN doses (1.25, 2.5, 5, or 10 mg/kg) was examined in adult Syrian hamsters observed for life. The minimal effective dose (threshold dose) for a neoplastic response, reflected by the induction of papillary polyps in the larynx and/or trachea, was 1.03 mg/kg. The first neoplasm occurred at 19 wk in the highest dose group. No

treatment-related tumors were found in other segments of the respiratory epithelium or in other tissues. (10 refs)

- 79-4992 Antigen Characteristics of Nitrosamine-induced Urinary Bladder Cancer in Rats. (Eng) Hashimoto, Y. (Tokyo Biochemical Res. Inst., Takada 3-41-8, Toshima-ku, Tokyo 171, Japan); Kitagawa, H. S. *Gann* 70(3): 305-314; 1979.

Tumor-associated or tumor-specific antigens expressed on urinary bladder cancer cells of transplantation and tissue culture lines that originated from tumors induced by N-butyl-N-(4-hydroxybutyl) nitrosamine in ACI/N rats were studied. Tumor-specific transplantation antigen was determined by the transplantability of cancer cells into syngeneic rats that had been immunized with the respective cancer cells. Two of six bladder cancer lines showed high tumor-specific transplantation antigenicity (H-A); the antigenicities of the other four lines were low or undetectable. Cross-resistance to transplantation immunity was observed in the two H-A lines but not in the other lines. Cell-mediated cytotoxicity was assayed by the micro-test plate method. Lymphoid cells from ACI rats hyperimmunized with cancer cells of a H-A line showed marked cytotoxicity against cancer cells of the immunizing line but not to cells of the other bladder cancer lines, including another H-A line that induced cross-resistance to transplantation immunity. Tumor-associated cell-surface antigen was detected by a membrane immunofluorescence test with serum that was raised in an allogeneic Donryu rat by the H-A bladder cancer and absorbed with normal ACI rat tissues. The absorbed serum gave positive membrane fluorescence to cancer cells of the immunizing line and two other bladder cancer lines but not to cells of the other four bladder lines and ACI tumors other than bladder cancer. The common antigen detected by the serological method was not reflected either in the transplantation immunity or cell-mediated cytotoxicity of the immune lymphoid cells. (25 refs)

- 79-4993 Animal Model: Carcinoma of the Urinary Bladder, Induced in Fischer Rats by N-[4-(5-Nitro-2-furyl)-2-thiazolyl]formamide. (Eng) Cohen, S. M. (Dept. Pathology, St. Vincent Hosp., Worcester, MA 01604); Friedell, G. H. *Am J Pathol* 95(3): 849-852; 1979.

The development of carcinoma of the urinary bladder in male inbred Fischer 344 rats given N-[4-(5-nitro-2-furyl)-2-thiazolyl]formamide (FANFT, 0.2% in the diet starting from weaning) is described. The FANFT-induced tumors resemble human bladder carcinoma in several ways. Most of the lesions are of transitional cell type and papillary, although most advanced tumors are polypoid masses protruding into the lumen (a fairly uncommon form of human

bladder cancer). As with the human disease, the FANFT-induced lesions progress from epithelial hyperplasia to noninvasive carcinoma, invasion, and eventually distant metastases. Hematuria is a frequent early sign in both species. Pleomorphic microvilli represent a marker of irreversibility in the rat bladder epithelium proliferation in response to the carcinogen, and comparable changes are seen in human tumors. Pleomorphic microvilli are also seen on exfoliated bladder epithelial cells from human and animal subjects. The rat model may be useful for the investigation of possible promoting and initiating agents. (11 refs)

- 79-4994 Chromosome Mutations and Chromosome Stability in Children Treated with Different Regimens of Immunosuppressive Drugs. (Eng) Schuler, D. (Second Dept. Paediatrics, Semmelweis Univ. Medical Sch., Budapest, Hungary); Dobos, M.; Fekete, G.; Miltenyi, M.; Kalmar, L. *Hum Hered* 29(2): 100-105; 1979.

The chromosome mutations and the number of sister-chromatid exchanges (SCEs) induced by different kinds of immunosuppressive drugs were investigated based on data from 43 children and five adults with renal disease and 19 control children. The number of chromosome aberrations after any treatment was higher than the pretreatment frequency. High doses of cyclophosphamide (CPA) or a combination vinblastine-CPA, chlorambucil 6-mercaptopurine (6-MCP), and prednisolone gave the highest frequencies of aberrations. High and low doses of all drugs except 6-MCP gave different effects. Increased SCE frequencies were found after treatment with high doses of CPA or 6-MCP. (24 refs)

- 79-4995 Acute Nonlymphocytic Leukemia (Letter to Editor). (Eng) Reimer, R. R. (Cleveland Clinic Foundation, Cleveland, OH 44106); Groppe, C. W. *Ann Intern Med* 90(6): 989; 1979.

A 56-yr-old woman who had received preoperative pelvic radiation (5,000 rads) for adenosquamous carcinoma of the endometrium followed postsurgery by doxorubicin and cyclophosphamide (totals of 700 and 12,600 mg, respectively, over 8 mo) developed acute myelogenous leukemia approx 1 yr after the chemotherapy was stopped. The leukemogenic potential of such combined modality therapy remains to be quantitated. (4 refs)

- 79-4996 Metronidazole Exhibits No Cytogenetic Effect in the Micronucleus Test in Mice or on Human Lymphocytes in Vitro. (Eng) Hartley-Asp, B. (Res. Labs., AB Leo, S-251 00 Helsingborg, Sweden). *Mutat Res* 67(2): 193-196; 1979.

The cytogenetic activity of metronidazole (MN) on peripheral human lymphocytes (PHL) in vitro and on mouse polychromatic erythrocytes (PE) in vivo was studied. PHL were incubated for 72 hr in the presence of MN (500, 1,000, or 10,000 $\mu\text{g}/\text{ml}$) or medium alone. At each concentration, 1,000 cells were analyzed for mitotic frequency and 100 metaphase plates for chromosome breakage. There was no significant difference in the mitotic index or the number of chromosome breaks between control and treated cells. NMRI mice received a total of 100-3,000 mg/kg MN (2 po doses 24 hr apart) and cytogenetic damage was evaluated by the micronucleus test. MN did not produce a micronucleus frequency outside that of the control range (0.09%-0.32%). Methylmethane sulfonate (positive control) produced sharp increases in micronucleus frequency at doses ranging from 40 to 100 mg/kg (2 ip injections 24 hr apart). The micronucleus frequency in the PE of mice given MN (700-7,000 mg/kg) in 7 po doses 24 hr apart did not exceed that of controls. It is suggested that the absence of cytogenetic damage in vivo and in vitro in mammalian and human cells may be due to generally ample oxygenation of normal cells and, therefore, a lack of active metabolites. (17 refs)

- 79-4997 Synthesis of α -Acetoxy-N-nitroso-4-[^3H]-pyrrolidine. (Eng) Saavedra, J. E. (Chemical Carcinogenesis Program, NCI Frederick Cancer Res. Program, Frederick, MD 21701); Hecker, L. I.; Farrelly, J. G. *J Labelled Compd Radiopharm* 16(3): 415-420; 1979.

During studies of the chemistry and mechanism of carcinogenesis of nitrosopyrrolidine, it was necessary to prepare tritium-labeled α -acetoxy-N-nitroso-4-[^3H]-pyrrolidine (III) as a precursor to 2-hydroxy-4-[^3H]-tetrahydrofuran. The two-step synthesis of III from commercially available l-proline-4-[^3H](I) is described. I was nitrosated in aqueous hydrochloric acid to N-nitroso-4-[^3H]-l-proline (II). Decarboxylation of II with lead tetraacetate in methylene chloride at 45 C for 10 hr in 1.2 equivalents of pyridine gave III in an overall yield of 23%. The product was purified by silica gel column chromatography and further purified before use in the metabolic studies by high-pressure liquid chromatography. (11 refs)

- 79-4998 Induction of Sister Chromatid Exchanges in the Central Mudminnow Following In Vivo Exposure to Mutagenic Agents. (Eng) Kligerman, A. D. (Dept. Pathology, Duke Univ. Medical Center, Box 3156, Durham, NC 27710). *Mutat Res* 64(3): 205-217; 1979.

The central mudminnow (*Umbra limi*) was used as a model in vivo system to study sister-chromatid exchange (SCE) induction after ip administration of a direct-acting mutagen and a promutagen. In addition, mudminnows were used to

investigate SCE induction caused by the addition of a mutagenic dye to their laboratory aquatic environment. Five days after the injection of 500 $\mu\text{g}/\text{g}$ 5-bromodeoxyuridine, SCE rates were low in the gills (2.0-3.3 SCE's/metaphase), kidneys (2.6-3.4), and intestines (3.7-4.5). However, after injection of 5-103 $\mu\text{g}/\text{g}$ methylmethanesulfonate (MMS) or 0.3-22 $\mu\text{g}/\text{g}$ cyclophosphamide (CP), large, linear, dose-dependent increases in SCE rates were observed in all tissues examined. CP induced two to four times more SCE's than MMS. When neutral red dye was added to the aquarium water (0.01-12.5 ppm), the mudminnow concentrated the dye in its gill and kidney tissues. The dye caused significant increases in SCE rates at levels of <0.1 ppm. However, the dye concentration in the tissues did not correlate with SCE rate. In fact, the kidneys, which had the highest dye concentrations, had the lowest SCE rates of the tissues examined. The results demonstrate that the mudminnow can be used as a sensitive indicator of substances that induce SCE (31 refs)

- 79-4999 DNA Damage and Repair Induced by Diazoacetyl Derivatives of Amino Acids with Different Mechanism of Cytotoxicity. Correlations with Mutagenicity and Carcinogenicity. (Eng) Brambilla, G. (Istituto di Farmacologia, Universita di Genova, Viale Benedetto XV, 2, I-16132 Genoa, Italy); Cavanna, M.; Carlo, P.; Finollo, R.; Sciaba, L.; Parodi, S.; Bolognesi, C. *J Cancer Res Clin Oncol* 94(1): 7-20; 1979.

Eight synthetic N-diazoacetyl amino acids, prepared by inserting a diazoacetyl group onto the α -nitrogen of a natural amino acid, and two natural diazoacetyl amino acids, azaserine (O-diazoacetyl-L-serine) and 6-diazo-5-oxo-L-norleucine (DON), were studied autoradiographically for their capacity to induce DNA repair synthesis in BALB/c mouse kidney cells cultivated in vitro. Dose-dependent unscheduled DNA synthesis occurred in cells treated with the eight N-diazoacetyl derivatives, but not in cells exposed to approx equitoxic concentrations of azaserine and DON. Azaserine and DON, unlike the N-diazoacetyl derivatives, did not alkylate γ -(4-nitrobenzyl)pyridine to an appreciable extent. When DNA damage (single-stranded breaks or weak points in alkali) was measured by the sensitive alkaline elution technique, N-diazoacetyl-glycine amide was found to be about four times as potent as azaserine and about 12 times as potent as DON on a molar basis, but it was about 800 and 17,000 times as potent as azaserine and DON, respectively, by extrapolating to equitoxic concentrations. Carcinogenicity and mutagenicity seem mainly to be associated with the capacity for inducing DNA damage. (49 refs)

- 79-5000 Action of Nitrofurans on *E. Coli* Mutation and Induction and Repair of Daughter-Strand Gaps in DNA. (Eng) Lu, C. (Dept. Biochemistry, McMaster Univ., Hamilton, Ontario, Canada); McCalla, D. R.; Bryant, D. W. *Mutat Res* 67(2): 133-144; 1979.

In the "treat and plate" tryptophan reversion assay, the antibacterial and mutagenic potency of nine nitrofurans in *Escherichia coli* varied over almost 5 orders of magnitude. The relative toxicities were as follows: N-(5-nitro-2-furyl)-thiazolyl)formamide (FANFT) > 2-(2-furyl)-3-(5-nitro-2-furyl) acrylamide (AF2) > 2-amino-4-(5-nitro-2-furyl) thiazole > furazolidine > furagin >> nitrofurantoin > nitrofurazone >> methylnitrofuroate >> nitrofuroic acid. In general, mutagenic activity paralleled toxicity. At concentrations corresponding to their LD50's, the compounds induced mutations at frequencies that ranged from $2.5/10^6$ survivors for FANFT to $130/10^6$ survivors for furagin (NF416). The observed differences in antibacterial and mutagenic activity are apparently not due to lack of activation of the weaker agents, since the two most potent agents were reduced somewhat more slowly than many of the less active agents. The relative sensitivities of AF2 of strains WP2, WP2 *uvrA*, CM561 (*lexA*) and CM571 (*recA*) to the antibacterial effects of AF2 were 1, 1.6, 3, and 7. With nitrofurazone, the relative sensitivities were 1, 1, 25, and 50. The *uvrA* strain was six- to sevenfold more mutable with both these agents than was WP2. No increase over the spontaneous mutation frequency was observed when *recA* or *lexA* strains were exposed to AF2 or nitrofurazone in these experiments. When wild-type or *uvrA* bacteria containing nitrofurantoin-induced lesions replicated their DNA in drug-free medium in the presence of [³H]thymidine for 5 min, the label was found in low mol-wt DNA, indicating that daughter-strand gaps were formed. During subsequent incubation in nonradioactive medium, the mol wt of the DNA increased to the control value. A *recA* strain (which was very sensitive to the lethal effects of AF2 and nitrofurazone) lacked the ability to repair daughter-strand gaps caused by nitrofurantoin-induced lesions. (26 refs)

- 79-5001 Production of Proliferative Lesions in Gastric Mucosa of Albino Mice by Oral Administration of N-Methyl-N'-nitro-N-nitrosoguanidine. (Eng) Sigaran, M. F. (Dept. Pathology, Sch. Medicine, Univ. Costa Rica at Hospital Mexico, San Jose, Costa Rica); Con-Wong, R. *Gann* 70(3): 343-352; 1979.

Ten groups of four Swiss albino mice were administered N-methyl-N'-N-nitrosoguanidine (MNNG: 100 µg/ml) in their drinking water for varying periods of time up to 68 wk, to determine whether there is a relationship between the quantity of mutagen ingested and the presence of proliferative mucosal lesions in the stomach or other lesions in various parts of the body. Intramucosal carcinomas occurred in 2/4 mice given MNNG for 68 wk, 2/4 mice given MNNG for 65 wk, and in 1/4 mice given MNNG for 54 wk. In the remaining groups of mice, which received MNNG for shorter periods of time, lesions occurred in a total of nine animals. These included foci of typical and atypical hyperplasia, erosion of the mucosa, and, in one animal, an adenomatous polyp. The lesions in all 10 groups did not demonstrate the sequence described by others; ie,

regenerative glandular hyperplasia, adenomatous hyperplasia, and adenocarcinoma. Beneath the diverse neoplastic lesions there was a predominantly inflammatory mononuclear infiltration with just a few polymorphonuclear cells. This response was not due to a local irritation caused by MNNG, and it was not present during the first weeks of the experiment. The reaction may represent an immunological response of the host to the development of neoplasia. Contrary to findings in humans, intestinal metaplasia preceding or accompanying the neoplasia was an inconsistent and infrequent alteration. (32 refs)

- 79-5002 Promotion of Epithelial Keratinization by N-Methyl-N'-nitro-N-nitrosoguanidine in Rat Forestomach in Organ Culture. (Eng) Fukamachi, H. (Zoological Inst., Univ. Tokyo, Tokyo 113, Japan); Takayama, S. *Experientia* 35(5): 666-668; 1979.

The effect of N-methyl-N'-nitro-N-nitrosoguanidine (MNNG; 1, 3, or 5 µg/ml for 1 hr) on the epithelial differentiation of the fetal (16.5 days) rat (inbred Fischer 344/DuCrj strain) forestomach in organ culture was studied. In explants treated with 5 µg/ml MNNG, keratinization was first noted on day 3, and all the epithelium was keratinized on day 5. In explants treated with 3 µg/ml MNNG, epithelial keratinization was first noted on day 4, and the process of keratinization was completed on day 6. Explants treated with 1 µg/ml MNNG showed a time-course of epithelial differentiation similar to that of untreated control tissue. The data indicate that MNNG promotes epithelial differentiation in the fetal rat forestomach in organ culture. (7 refs)

- 79-5003 A ¹³C NMR Investigation of Restricted Rotation and Dimerization in p-Substituted Nitrosobenzenes. (Eng) Cox, R. H. (Natl. Inst. Environmental Health Sciences, P.O. Box 12233, Research Triangle Park, NC 27709); Hamada, M. *Org Magn Reson* 12(5): 322-325; 1979.

The barrier to internal rotation in a series of p-substituted nitrosobenzenes was determined by variable temperature ¹³C nuclear magnetic resonance. Substituent effects on the barrier were similar to those observed for acetophenones and benzaldehydes, and dimerization of the nitrosobenzenes was observed at low temperature for substituents CH₃, Cl, and H. The barrier height is discussed in terms of contributions from resonance effects. (28 refs)

- 79-5004 Enhancement of Reductive Metabolism of p-Nitrobenzoate and Nitrazepam in Isolated Perfused Rat Liver by Ethanol. (Eng) Jonen, H. G. (Dept. Pharmacology, Univ. Mainz, D-6500 Mainz, W. Germany). *Drug Metab Dispos* 7(3): 176-180; 1979.

The reductive metabolism of p-nitrobenzoate in the isolated perfused rat liver was enhanced fivefold in the presence of 38 mM ethanol. Ethanol failed to increase hepatic nitroreduction when alcohol dehydrogenase activity was inhibited by pyrazole. Ethanol also enhanced the formation of the 7-amino derivative from nitrazepam, whereas the formation of 7-acetylamino derivative remained unchanged. (52 refs)

79-5005 Chemicals Which Revert All Commonly Used *Salmonella Typhimurium* Tester Strains. (Eng) McKee, R. H. (Litron Labs., 1351 Mt. Hope Avenue, Rochester, NY 14620); Tometsko, J. G.; Tometsko, A. M. *Mutat Res* 67(2): 183-187; 1979.

4-Fluoro-3-nitrophenylazide (FNPA) and dinitrophenyl azide (DNPA) induced reversions in five tester strains (TA98, TA100, TA1535, TA1537, and TA1538) of *Salmonella typhimurium* commonly used in the Ames test. FNPA and DNPA reverted the five strains in the dark, without the incorporation of liver microsomes; mutagenic induction was linear with all strains at FNPA or DNPA concentrations ranging from 100 to 400 µg/plate. At lower mutagen levels FNPA yielded 0.5 revertant per nanomole with TA100, (nmol) and DNPA yielded 10 revertants/nmol with TA98 and 5 with TA100. The reversion of TA100 and TA1535 by both FNPA and DNPA indicates a base-pair substitution mutagenic activity. The reversion of both the TA98/TA1538 pair and the TA1537 strain indicated frameshift-inducing mutagenic activity. FNPA or DNPA did not significantly enhance the reversion of the WP2s mutant of *Escherichia coli* at drug concentrations ranging from 1 to 400 µg/plate; this suggests that the base-pair substitution activity is restricted to specific types or sites. No enhancement of WP2s reversion in the presence of 40 µg sodium azide/plate was observed. These results suggest that the base-pair substitution mutagenic activity of FNPA and DNPA involves sites affected by sodium azide, whereas the frameshift mutagenic activity may be a more general effect. To rule out the possibility that the mutagenicity of FNPA and DNPA could be due to contamination with sodium azide, FNPA was repeatedly dissolved in ether, passed through a wool column, and dried. The purified material was significantly mutagenic. Conversely, when an equal amount of sodium azide was treated in the same way, the product showed no mutagenicity. Thus, the base-pair mutagenic activity is associated with FNPA rather than with a contaminant. (14 refs)

79-5006 Analgesic-associated Urinary-Tract Tumors (Letter to Editor). (Eng) Burnett, K. R. (Veterans Admin. Medical Center, Long Beach, CA 90822); Miller, J. B.; Greenbaum, E. *Ann Intern Med* 90(6): 994; 1979.

A Grade V transitional cell carcinoma was diagnosed in a 65-yr-old man who presented with a long history of phenacetin abuse and difficulty in voiding. Microscopic hematuria and pyuria plus kidney changes consistent with interstitial nephropathy were found initially. Four months later, total gross hematuria and a filling defect in the left renal pelvis were discovered. The tumor, which had an unusually rapid growth rate, may be partially or wholly due to the carcinogenicity of phenacetin. (2 refs)

79-5007 The Distribution of Carcinogens, 4-Nitroquinoline-1-oxide and 4-Hydroxyaminoquinoline-1-oxide, in the Nervous System and Its Possible Neurotoxicological Significance. (Eng) Takasu, T. (Dept. Neurology, Inst. Brain Res., Univ. Tokyo, 7-3-1 Hongo, Bunkyo-ku, Tokyo, Japan). *Experientia* 35(5): 668-670; 1979.

The distribution of the carcinogens 4-nitroquinoline-1-oxide (4NQO) and 4-hydroxyaminoquinoline-1-oxide (4HAQO) in the nervous system of adult male ddY mice following iv administration was studied. After 5 hr, the uptake of 4NQO by the CNS gray matter exceeded that by any other parenchymal organ and was much higher than that by the blood. The uptake by the cerebellar cortex and white matter was relatively low and that by the spinal dorsal root ganglia was quite low compared with the central gray matter. The uptake of 4HAQO by the brain and spinal cord was relatively low and that by the spinal dorsal root ganglia was high. The level of uptake by the trigeminal ganglia was also high. The results suggest that a considerable part of the 4NQO entering the CNS tissue parenchyma was taken up by the neuronal cell bodies, axons, and/or dendrites of the central gray matter. The data also suggest that 4HAQO and its metabolites in the blood cannot easily pass into the CNS tissue parenchyma. (9 refs)

79-5008 Effect of Aluminum Chloride on Binding of 4-Hydroxyaminoquinoline 1-Oxide to Nucleotides. (Eng) Yamane, Y. (Faculty Pharmaceutical Sciences, Chiba Univ., 1-33, Yayoi-cho, Chiba 260, Japan); Ohtawa, M. *Gann* 70(3): 361-364; 1979.

The effect of aluminum chloride (AC) and various other metals on the binding of 4-hydroxyaminoquinoline 1-oxide (4-HAQO) to dd mouse lung DNA, RNA, and various homopolyribonucleotides was examined in vitro, in the presence of seryl-AMP. AC markedly inhibited the binding of 4-HAQO to DNA, RNA, polyadenylic acid, and polyguanylic acid, resulting in binding rates that were 46%, 56%, 53%, and 18% of that of controls, respectively. The binding of 4-HAQO to polycytidylic acid and polyuridylic acid was not inhibited. Thus, the effect of AC is assumed to be due to an inhibition of the binding of 4-HAQO to purine base(s), especially guanine. Compared with the

other metals tested, AC had the strongest inhibitory effect, with the effects of the others decreasing in the order $\text{Cu}^{2+} > \text{Zn}^{2+} > \text{Mn}^{2+} > \text{Ni}^{2+} > \text{Co}^{2+} > \text{Mg}^{2+}$. Fe^{3+} showed hardly any inhibition. It is concluded that inhibition of the binding of 4-HAQO to guanine is one of the factors in the inhibition of 4-nitroquinoline 1-oxide-induced lung cancer development by AC. (15 refs)

- 79-5009 The Application of Mitotic Gene Conversion in *Saccharomyces cerevisiae* in a Pattern of Four Assays, In Vitro and In Vivo, for Mutagenicity Testing. (Eng) Siebert, D. (Forstbotanisches Institut, Universitat Freiburg, Freiburg, E. Germany); Bayer, U.; Marquardt, H. *Mutat Res* 67(2): 145-156; 1979.

The induction of mitotic gene conversion of the nitrofurantoin derivatives nitrofurantoin (N-(5-nitro-2-furfuryliden)-1-aminohydantoin), nifurprazinum (1-(5-nitro-2-furyl)-2-(6-amino-3-pyridazyl)-ethylenhydrochloride) and FANFT (2-formylamino -4-(5-nitro-2-furyl) thiazole) was investigated in the D4-RDII strain of *Saccharomyces cerevisiae* (heteroallelic at the gene loci *ade* and *trp5*, respiration-deficient). A battery of tests was applied: direct action of the substances in yeasts, the liver microsome test in vitro, the host-mediated assay, and the urinary assay. From the various combinations of positive and negative results, additional pharmacokinetic conclusions were drawn. The three nitrofurantoin derivatives gave positive results by direct action and in the urine of BDII rats. The addition of liver microsomes of NMRI mice in the in vitro test reduced the number of induced mitotic gene conversions. In the first hour, much of the nitrofurantoin given po to rats was excreted in the urine, as shown by a high genetic activity. Nifurprazinum and FANFT were excreted to a lesser extent or more slowly. Addition of glucuronidase/arylsulfatase reduced the genetic activity of nitrofurantoin in the urine, increased the activity of nifurprazinum, and was without any effect in the case of FANFT. In the host-mediated assay, only nitrofurantoin gave positive results. These results seem to be a consequence of the different excretion patterns of the nitrofurantoin derivatives. (31 refs)

- 79-5010 N-Nitroso Compound Contaminants in Prescription and Nonprescription Drugs. (Eng) Krull, I. S. (New England Inst. Life Sciences, 125 Second Ave., Waltham, MA 02154); Goff, U.; Silvergleid, A.; Fine, D. H. *Arzneim Forsch* 29(6): 870-874; 1979.

Gas chromatography-thermal energy analysis and high-pressure liquid chromatography-thermal energy analysis

revealed that N-nitroso compounds were not present in most of 73 pharmaceutical products tested. However, the analysis suggested the possible presence of N-nitroso impurities in three prescription drugs--phenylzine sulfate, imipramine HCl, and nitrofurantoin-- at levels of 81, 68, and 40 ppb, respectively, and in two over-the-counter cold remedies at 126 and 406 ppb. (17 refs)

- 79-5011 Carcinogenic Effect of 3-(Dihydroxymethyl)amino-6-(5-nitro-2-furylethenyl)-1,2,4-triazine Present in Panfuran-S in Mice. (Ger) Konishi, Y. (Dept. Oncological Pathology, Medical Univ., 840 Shi-jochi, Nara 634, Japan); Aoki, Y.; Takahashi, S.; Inui, S.; Denda, A.; Takita, M. *Onkologie* 2(1): 41-42; 1979.

The carcinogenicity of 3-(dihydroxymethyl)amino-6-(5-nitro-2-furylethenyl)-1,2,4-triazine (DHNT), present in the antimicrobial agent Panfuran-S, was studied in dd mice. The animals received Panfuran-S in the diet: the DHNT dose was 0 ppm in Group 1 (controls), 175 ppm in Group 2, 350 ppm in Group 3, 700 ppm in Group 4, 1,750 ppm in Group 5, and 3,500 ppm in Group 6. The tumor incidence was determined among survivors at 35 wk. The tumor incidence was 0 in the control group. Esophageal papillomas were found in 2/28 Group 5 and 4/17 Group 6 mice. Esophageal carcinomas were found in 3/28 Group 5 mice. Forestomach papillomas were found in 5/20 Group 2, 15/29 Group 3, 13/26 Group 4, and 4/28 Group 5 mice. Forestomach carcinomas were found in 3/29 Group 3, 9/26 Group 4, 20/28 Group 5, and 17/17 Group 6 mice. Adenocarcinomas of the duodenum and jejunum were found in Group 5 (8/28) and Group 6 (10/17). Gallbladder carcinomas were found in 2/28 animals in Group 5 and 1/17 in Group 6. The keratinizing squamous epithelial carcinomas showed numerous mitoses, and they metastasized into the liver, lungs, and regional lymph nodes and infiltrated the tissues surrounding the stomach and pancreas. The findings suggest that the carcinogenic effect of Panfuran-S is due to DHNT. (7 refs)

- 79-5012 Evaluation of the Mutagenicity of Aminoglycoside Antibiotics in *Salmonella typhimurium* and *Saccharomyces cerevisiae*. (Eng) Koeda, T. (Central Res. Labs., Meiji Seika Kaisha, Ltd., Morooka, Yokohama, Japan); Hirano, F. *J Antibiot (Tokyo)* 32(6): 607-609; 1979.

The aminoglycoside antibiotics kanamycin, aminodeoxykanamycin, dibekacin, ribostamycin, amikacin, gentamicin, and tobramycin were not mutagenic when tested in the *Salmonella typhimurium* and *Saccharomyces cerevisiae* systems. (5 refs)

- 79-5013 Intranuclear Rodlets in Undifferentiated Carcinomas of Salivary Glands in Strain A Mice in a Study Involving a Tobacco Specific Nitrosamine, N-Nitrosornicotine. (Eng) Hirota, N. (Naylor Dana Inst. Disease Prevention, American Health Foundation, Valhalla, NY 10595). *Cancer Lett* 6(6): 365-369; 1979.

Strain A/J female mice (6-8 wk old) were injected with the tobacco-specific nitrosamine N-nitrosornicotine (NNN; 1 mg ip 3x/wk for 22 injections), and observed for 30 wk after the last injection. Salivary gland tumors which occurred in 2/44 mice, were examined by electron microscopy. Both tumors were undifferentiated carcinomas consisting of spheroidal and fusiform spindle cells. Ultrastructurally, distinctive intranuclear rodlets (INR) were observed in 1/5-10 cells. There were two types of rodlets; one was composed of fibrillar filaments arranged in bundles and the other was much thicker, branching in form without arrangement in bundles and was closely associated with nuclear chromatin or nucleoli. No rodlet-like inclusions were detected in other salivary tissues from either the NNN-treated or untreated groups and no viral particles were observed. The presence of INR in non-neuronal neoplastic cells may indicate a pathological process similar to nuclear body formation as seen in a variety of tumor cell types. (14 refs)

- 79-5014 Mutagenic Activity of Marihuana Smoke Condensates. (Eng) Busch, F. W. (Sch. Public Health, Univ. California, Berkeley, CA 94720); Seid, D. A.; Wei, E. T. *Cancer Lett* 6(6): 319-324; 1979.

The mutagenic activity of marihuana smoke condensates was evaluated in the Ames bioassay and compared to that of tobacco smoke condensates. Acetone extracts of uncombusted marihuana leaves were not mutagenic when tested, with and without liver homogenates (S-9) from Aroclor 124-pretreated rats, in *Salmonella typhimurium* strain TA98 at doses up to 1 mg/plate. Marihuana smoke condensates were mutagenic in TA98 in the presence of S-9. No significant mutagenic activity was observed in TA98 in the absence of S-9 or in strains TA1535 and TA1537, with and without S-9. The strain specificity indicates that frameshift mutagens were the predominant species. For standardized tobacco samples, marihuana condensates were approx 60% as mutagenic as tobacco condensates.

For freshly prepared samples, both were about equally mutagenic. It is concluded that the mutagenic activity of marihuana smoke condensates is comparable and certainly not greater than that of tobacco condensates. (18 refs)

- 79-5015 The Effects of Experimental Exposure to Tobacco Smoke on the Oxidative Metabolism of Alveolar Macrophages. (Eng) Drath, D. B. (Dept. Biological Chemistry, Harvard Medical Sch., Boston, MA); Karnovsky, M. L.; Huber, G. L. *J Reticuloendothel Soc* 25(6): 597-604; 1979.

The effects of tobacco smoke on the oxidative metabolism and related enzymes of alveolar macrophages (AM) were studied. When exposed for 30 days to tobacco smoke, CD rat AM showed a doubling of oxygen consumption (QO_2) and hydrogen peroxide H_2O_2 release during phagocytosis. In addition, NADP⁺-dependent glucose oxidation was depressed although superoxide (O_2^-) release was unaffected. The glutathione cycle, thought to link peroxide-generating reactions with hexose monophosphate shunt activity, was unaffected by tobacco smoke. Glutathione peroxidase was present to the extent of 27.2 units/mg protein and 24.3 units/mg in the AM of control and smoke-exposed rats, respectively. The corresponding levels for glutathione reductase were 1.8 units/mg protein and 1.5 units/mg. A peroxidase similar to the myeloperoxidase of neutrophils was not detectable in AM. Catalase activity, although not affected by tobacco smoke, was present to the extent of 3.0 units/mg protein and was found in both a cytoplasmic and granule-rich component, with the latter latent to the extent of an order of magnitude. Superoxide dismutase activity was decreased 35% by smoke exposure. (31 refs)

- 79-5016 Effect of Smoking on the Recurrence of Malignant Melanoma. (Eng) Shaw, H. M. (Melanoma Clinic, Sydney Hosp., Macquarie St., Sydney, New South Wales 2000, Australia); Milton, G. W.; McCarthy, W. H.; Farago, G. A.; Dilworth, P. *Med J Aust* 1(6): 208-209; 1979.

The influence of smoking on the recurrence of malignant melanoma (MM) was studied in 1,908 Australian MM patients. At the time of diagnosis, 45.3% of the men and 28.1% of the women patients were smokers. Sites of primary lesions were similar in smokers and nonsmokers, but significantly more smokers than nonsmokers were <50 yr of age ($p < 0.01$ for men; $p < 0.001$ for women). There was a nonsignificant tendency for more smokers than nonsmokers to have regional lymph node or distant metastases at first presentation. Among the men with Stage

I MM diagnosis, the proportion of patients who were disease-free 5 yr later was significantly lower ($p < 0.02$) among smokers than nonsmokers (55% of 315 vs 63.0% of 403). A similar effect was not observed in the women patients. (8 refs)

- 79-5017 Carcinoma of the Larynx in Hamsters Exposed to Cigarette Smoke. Animal Model: Susceptible Inbred Line of Syrian Hamsters (BIO 15.16). (Eng) Homburger, F. (Bio-Res. Inst., Cambridge, MA); Soto, H.; Althoff, J.; Dalquen, P.; Heitz, P. *Am J Pathol* 95(3): 845-848; 1979.

The production of carcinoma of the larynx in susceptible inbred Syrian hamsters exposed to cigarette smoke is described. These cancers were indistinguishable by light microscopy from cancers of the larynx in heavily smoking human subjects. The same precancerous stages could be discerned in the lesions from both species. It may be assumed that the etiology of the cancers is the same in both species and the hamster model could be used to study alcohol as a cocarcinogen for laryngeal cancer. (12 refs)

- 79-5018 Implantation of Cigarette Smoke Condensate in the Lungs of Syrian Golden Hamsters. (Eng) Ketkar, M. B. (Abteilung für experimentelle Pathologie, Medizinische Hochschule Hannover, Karl-Wiechert-Allee 9, D-3000 Hannover 61, W. Germany); Haas, H.; Althoff, J. *J Cancer Res Clin Oncol* 94(1): 111-114; 1979.

The carcinogenic effects of benzo(a)pyrene (BP, 0.05 or 0.1 mg), cigarette smoke condensate (CSC, 50 mg), and the latter's nitromethane fraction (NMF, 5, 15, or 25 mg) were studied following the implantation of the substances in wax pellets in the lungs of male Syrian golden hamsters. There were no significant differences in survival rate or body wt after the different treatments. Round black or yellow nodules were found on the lung surface at the implantation site. A granulomatous inflammatory response was also observed at the site of implantation. Bronchiogenic adenomas developed in 1/31 animals given CSC and 5/63 animals treated with 15 or 25 mg NMF. Pleomorphic sarcomas, which spread throughout the lung and into the opposite lung, developed in 6/64 animals treated with BP. Tumors occurring at other sites were unrelated to treatment. (6 refs)

- 79-5019 Carcinogenicity of a Composite Organic Extract of Urban Particulate Atmospheric Pollutants Following Subcutaneous Injection in Infant Mice. (Eng) Epstein, S. S. (Sch. Public Health, Univ. Illinois Medical Center, Chicago, IL); Fujii, K.; Asahina, S. *Environ Res* 19(1): 163-176; 1979.

Studies of the carcinogenicity of atmospheric pollutants in mice were extended by investigating the effects of dose and time of administration of the extracts during the first 2 wk of life. Sc injection of a suspension of a composite organic (benzene) extract of particulate atmospheric pollutants into perinatal Swiss albino mice, at total doses of 5-40 mg, produced carcinogenic effects that were dose-related and related to the age of the mice at the time of injection. Injection within 1-7 days after birth resulted in a dose-related increase in the total tumor incidence and in the incidence of solitary pulmonary adenomas in both sexes. Additionally, the pollutant extracts induced multiple pulmonary adenomas, pulmonary adenocarcinomas, and lymphomas in males and females and hepatocellular carcinomas in males. The experiments indicated that 1- and 7-day-old mice are generally more sensitive than 14-day-old mice to carcinogens in organic extracts of air pollutants. (10 refs)

- 79-5020 Gas-Liquid Chromatographic Determination of Aniline Derivatives in Water. (Rus) Kulikova, G. S. (Inst. Chemistry, Ural Res. Center, Sverdlovsk, USSR); Kirichenko, V. E.; Pashkevich, K. I. *Zh Anal Khim* 34(4): 790-793; 1979.

A gas-liquid chromatographic assay for determining trace amounts of aniline derivatives in water is described. The compounds are extracted from water with benzene, converted into trifluoromethoxytetrafluoropropionic acid anilides, and chromatographed using a constant recombination-rate detector. The detection limit is 2.3×10^{-3} mg/liter, and the relative standard deviation is 0.02-0.04. (5 refs)

- 79-5021 Glutathione Adducts of N-Methyl-4-aminoazobenzene Formed In Vivo and by Reaction of N-Benzoyloxy-N-Methyl-4-aminoazobenzene with Glutathione. (Eng) Ketterer, B. (Courtauld Inst. Biochemistry, Middlesex Hosp. Medical Sch., London W1P 7PN, England); Kadlubar, F.; Flammang, T.; Carne, T.; Enderby, G. *Chem Biol Interact* 25(1): 7-21; 1979.

The formation of an N-methyl-4-aminoazobenzene-reduced glutathione adduct following the administration of N,N-dimethyl-4-aminoazobenzene (DAB, 50 mg, ip) to bile-duct cannulated Wistar rats was investigated. The reaction of N-benzoyloxy-N-methyl-4-aminoazobenzene with glutathione in vitro yielded one major and two minor aminoazo dye-glutathione adducts. The major adduct was 3-(glutathion-S-yl)-N-methyl-4-aminoazobenzene (3-GS-MAB) and one of the minor products was 2'-(glutathion-S-yl)-N-methyl-4-aminoazobenzene. The other minor adduct was tentatively identified as 4'-(glutathion-S-yl)-N-methyl-4-aminoazobenzene. Two aminoazo dye derivatives were isolated from DAB-treated rats: 3-GS-MAB, and a probable 4-aminoazobenzene-glutathione adduct. (34 refs)

79-5022 Mutagenicity and Irreversible Binding of the Hepatocarcinogen, 2,4-Diaminotoluene. (Eng) Aune, T. (Dept. Environmental Toxicology, Natl. Inst. Public Health, Oslo 1, Norway); Nelson, S. D.; Dybing, E. *Chem Biol Interact* 25(1): 23-33; 1979.

Mutagenicity of 2,4-diaminotoluene (DAT) in the *Salmonella* mutagenicity assay was increased with liver fractions from phenobarbital (PB) or β -naphthoflavone (BNF) treated rats. Substitutions of the hydrogens in the methyl group of 2,4-DAT with deuterium resulted in a decrease in mutagenicity. Incubation of rat liver microsomes with tritiated 2,4-DAT in the presence of NADPH led to the formation of irreversibly bound products to microsomal protein. The rates of binding were not increased using microsomes from PB or BNF-treated rats and was not altered by deuterium substitution in the methyl group. Addition of superoxide dismutase, glutathione (GSH) or rat liver supernatant reduced 2,4-DAT irreversible binding, whereas 2,4-DAT mutagenicity was unaffected by superoxide dismutase addition. Injection of tritiated 2,4-DAT 100 mg/kg to rats leads to its irreversible binding to liver protein and ribosomal RNA and to kidney protein in vivo. Protein binding was not increased after prior treatment with PB or BNF. No irreversible interaction of tritiated 2,4-DAT with DNA either in vitro or in vivo could be demonstrated. (24 refs)

79-5023 Neoplasms of the Forestomach in Mice Ingesting Dihydrosafrole. (Eng) Reuber, M. D. (Chemical Carcinogenesis Program, NCI Frederick Cancer Res. Center, Frederick, MD 21701). *Digestion* 19(1): 42-47; 1979.

The max tolerated doses of dihydrosafrole, safrole, and isosafrole were given by continuous po administration, starting at age 7 days, to male and female mice of two hybrid strains, (C57BL/6 x C3HAnf)_{F1} and (C57BL/6 x AKR)_{F1}. Hyperplasia and carcinomas of the forestomach were significantly increased in female mice of both strains and in male C57BL/6 x AKR)_{F1} mice given dihydrosafrole. By contrast, forestomach neoplasms were not increased in mice receiving safrole or isosafrole. Mice with stomach neoplasms generally did not have liver neoplasms. (15 refs)

79-5024 Determination of the Tumorigenic Potential of Methylene-bis-ortho-chloroaniline. (Eng) Kommineni, C. (Natl. Inst. Occupational Safety and Health, Robert A. Taft Labs., 4676 Columbia Parkway, Cincinnati, OH 45226); Groth, D. H.; Frock, I. J.; Voelker, R. W.; Stanovick, R. P. *J Environ Pathol Toxicol* 2(5, Special): 149-171; 1979.

The dose-response effect of methylene(bis)ortho-chloroaniline (MOCA), a widely used industrial chemical, in male

Sprague-Dawley rats ingesting semipurified protein-adequate (PA) and protein-deficient (PD) diets was determined, and the amount of urinary MOCA excreted at various dose levels was correlated with tumor induction. MOCA induced a wide spectrum of neoplasms in male rats fed either the PA (27% casein) or the PD (8% casein) diet. The concentrations of MOCA used were 125, 250, 500, and 1,000 ppm. Increasing doses of MOCA in either diet resulted in decreased survival times. MOCA induced pulmonary adenomas, adenocarcinomas, mammary gland adenocarcinomas, Zymbal gland carcinomas, hepatocellular carcinomas, and hemangiosarcomas. In both diet groups, the lungs were the most sensitive organs to the induction of neoplasms by MOCA. The incidence of primary pulmonary neoplasms in the lowest dose group was 6% ($p \leq 0.01$), but in the highest dose group it was 70% ($p \leq 0.01$). The hepatocellular carcinoma incidence in rats fed a PD diet + 500 ppm MOCA was 18%, whereas the incidence in rats fed a PA diet + 500 ppm MOCA was only 4%. The mean urinary concentration of MOCA in rats fed the lowest dose (125 ppm-PD) was 0.63 ppm, a concentration comparable to that measured in the urine of workers exposed to MOCA. (5 refs)

79-5025 Study of the Inducing Action of Benzo-5,6-flavone on Pulmonary Benzo(a)pyrene Monoxidase Activity. (Fre) Queval, P. (Laboratoire de Pathologie pleuropulmonaire, Hopital Laennec, 42 rue de Sevres, 75007 Paris, France); Beaumatin, J. *C R Acad Sci [D] (Paris)* 288(15): 1215-1217; 1979.

The induction of pulmonary benzo(a)pyrene monoxidase (BMO) activity by benzo-5,6-flavone (BF) as well as by other substances and ionizing radiation was studied in 6- to 12-mo-old Sprague-Dawley rats. Compared with untreated controls [0.63 unit (U)], induction of BMO was seen in rats treated with BF (3-50 mg/kg ip, or 100 mg/kg/day po for 6 days: 9.03-17.53 U), benzo(a)pyrene (BP: 12.5 mg/kg: 14.49 U), methylcholanthrene (2.5 mg/kg: 13.33 U), or radiation (6,000 Working-Level-Month: 14.5 U). (A WLM = 168 hr spent in an atmosphere containing ^{222}Rn and its daughters at a concentration of 1 WL/m³. A WL = an atmospheric concentration of 10^{-7} Ci/m³ ^{222}Rn in equilibrium with its daughters.) Although tobacco smoke and flavone (20 mg/kg) did not induce BMO, they enhanced the enzyme-inducing effect of BF and BP. The findings indicate that the noncarcinogen BF is an excellent inducer of BMO activity. (10 refs)

79-5026 Mutagenicity of Quercetin and Kaempferol on Cultured Mammalian Cells. (Eng) Maruta, A. (First Dept. Internal Medicine, 3-46 Urafune-cho, Minamiku, Yokohama 232, Japan); Enaka, K.; Umeda, M. *Gann* 70(3): 273-276; 1979.

The mutagenicity of quercetin (QC) and kaempferol (KF) was investigated in V79 Chinese hamster cells, with and without metabolic activation. Treatment of the cells for 2 days with 10, 20, or 50 $\mu\text{g/ml}$ QC in the absence of metabolic activation produced slight growth inhibition; treatment of the cells with 20 or 50 $\mu\text{g/ml}$ KF produced severe growth inhibition. The number of 8-azaguanine-resistant colonies increased significantly after the cells were exposed to 20 or 50 $\mu\text{g/ml}$ QC, and mutation frequencies increased in a dose-dependent manner. With KF, mutation frequencies increased only slightly at 20 or 50 $\mu\text{g/ml}$. Treatment of the cells with QC in the presence of a metabolic activation system decreased the number of survivors and slightly increased the number of 8-AZ-resistant cells. The mutation frequency increased with dose, and it was 12 higher than that of control cultures at 200 $\mu\text{g/ml}$ QC. With KF, calculated mutation frequencies also increased with dose because of the marked decrease of survivors, although there was no increase in the number of resistant cells. QC was several times more active than KF in the metabolic activation assay. The results suggest that QC must be metabolized for it to exert its mutagenic activity and that the V79 cells themselves have an enzymic activation system that metabolizes QC very slowly but cumulatively. - 79-5027 Cytogenetic Hazards from Agricultural Chemicals. (Eng) Panda, B. B. (Cytogenetics Lab., Dept. Botany, Berhampur Univ., Berhampur 760007, India); Sahu, R. K.; Sharma, C. B. *Mutat Res* 67(2): 161-166; 1979.

The responses of several mitotic systems to the β -exotoxin and δ -endotoxin protein from *Bacillus thuringiensis* were assayed as a sequel to test results of the exotoxin in *Allium*. The protein subunit of the δ -endotoxin had no effect on the root meristematic cells of *A. cepa*, *A. sativum*, or *Vicia faba*, with the exception of a mild mitodepression. The β -exotoxin, on the other hand, was C-mitotic in all these systems, and it also caused centromeric extension and clastogenesis in *A. sativum*. (29 refs)

- 79-5028 Mutagenic Activity of *Fusarium moniliforme* Isolates in the *Salmonella typhimurium* Assay. (Eng) Bjeldanes, L. F. (Dept. Nutritional Sciences, Univ. California, Berkeley, CA 94720); Thomson, S. V. *Appl Environ Microbiol* 37(6): 1118-1121; 1979.

A total of 33 isolates of *Fusarium moniliforme* from several food or feed crops were grown on sterile cracked corn, and chloroform-isopropanol extracts were assayed for mutagenic activity in the *Salmonella typhimurium*-microsome system. Tester strains TA98 and TA100 were used. Extracts of 21 of the isolates assayed against TA100 were mutagenic. The activities of seven of these extracts increased markedly with the incorporation of the liver

homogenate (S-9) into the assay. Seven of the 22 isolates assayed against TA98 were weakly active, with the liver homogenate having little effect on reversion rates. Isolation and characterization studies of the active compounds are in progress. (18 refs)

- 79-5029 Antibacterial Activity, DNA-attacking Ability and Mutagenic Ability of the Mycotoxin Zearalenone. (Eng) Boutibonnes, P. (Laboratoire de Physiologie bacterienne II, UER de Sciences, Univ. Caen, 14032 Caen Cedex, France); Loquet, C. *IRCS Med Sci (Cancer)* 7(4): 204; 1979.

In *Bacillus thuringiensis*, zearalenone induced cellular alterations and inhibited enzyme synthesis, sporulation, and growth rate. The mycotoxin also was positive in the *rec* assay (DNA-attacking ability) using *Bacillus subtilis*, but it was not mutagenic in the histidine(+) reversion assay using *Salmonella typhimurium*. - 79-5030 The 'Carry-Over' of Aflatoxin, Ochratoxin and Zearalenone from Naturally Contaminated Feed to Tissues, Urine and Milk of Dairy Cows. (Eng) Shreeve, B. J. (Central Veterinary Lab., Weybridge, Surrey KT15 3NB, England); Patterson, D. S.; Roberts, B. A. *Food Cosmet Toxicol* 17(2): 151-152; 1979.

Concentrated rations containing 385-1,925 μg zearalenone/kg or 317-1,125 μg ochratoxin A/kg were fed to two cows for 7 and 11 wk, respectively. Aflatoxin B₁ was fortuitously present in both rations at a concentration of 20 $\mu\text{g/kg}$. Residues of zearalenone, ochratoxin A, and aflatoxin B₁ were not detected in muscle, liver, kidney, serum, milk, or urine, but ochratoxin A (5 $\mu\text{g/kg}$) was detected in the kidneys of one cow, and aflatoxin M₁ (trace amounts to 0.6 $\mu\text{g/kg}$) was detected in the kidneys, milk, and urine of all animals. - 79-5032 Aflatoxin Contamination in Grains and Grain Products During the Dry Season in Guatemala. (Eng) de Campos, M. (Div. Food Control and Analysis, Inst. Nutrition Central America and Panama, Guatemala City, Guatemala); Olszyna-Marzys, A. E. *Bull Environ Contam Toxicol* 22(3): 350-356; 1979.

The incidence of aflatoxin contamination in grains and grain products obtained during the dry season in Guatemala was studied. Of the 264 samples analyzed, 17% were contaminated with aflatoxins and 8% exceeded the 20 ppb level of contamination. A greater incidence of contamination would be expected from samples collected during the rainy season. Aflatoxin B1 was found in all positive samples, aflatoxin G1 was found in corn, peanuts, rice, beans, and meat meal, and aflatoxin G2 was found only in rice and beans. The highest incidence of contamination (26%) was found in samples from the hot and humid region of the country compared with 7% contamination in samples from the hot and dry region and 2% contamination in samples from the cold or temperate and humid regions ($p < 0.05$). Moisture content of the samples was not correlated with aflatoxin contamination. The most important staple food, corn, showed 12% contamination; and rice, another staple, was also heavily contaminated. Only 1/26 samples of the second most important staple food, black beans, was contaminated. (17 refs)

79-5033 Impaired Phagocytosis by Heterophils from Chickens During Aflatoxicosis. (Eng) Chang, C. F. (Dept. Poultry Science, North Carolina State Univ., Raleigh, NC 27650); Hamilton, P. B. *Toxicol Appl Pharmacol* 48(3): 459-466; 1979.

The effects of graded concentrations of dietary aflatoxin (AF: 0, 0.625, 1.25, 2.5, 5.0, and 10.0 ppm) on the in vitro phagocytic and bactericidal abilities of heterophils from chickens were investigated. The mean, percentage, and rate of phagocytosis were reduced. Several heterophil populations were identified; 10% were unable to phagocytize (0 ppm), 15% were very sensitive to AF (0.625 ppm), 30% were resistant to AF (5 and 10 ppm), and about 45% were of intermediate sensitivity (1.25 and 2.5 ppm). Crossover experiments demonstrated that the cellular and serum factors required for optimal phagocytosis were impaired during aflatoxicosis and that the serum factor had the heat sensitivity of complement. Both spontaneous and chemotactic locomotion by heterophils were impaired. The heterophils from birds with aflatoxicosis that phagocytized bacteria had a reduced ability to kill the bacteria. Thus, a representative of the circulating phagocytes responsible in part for nonspecific host resistance has impaired function during aflatoxicosis. (40 refs)

79-5034 Portal Diversion Enhances Hepatocarcinogenesis Induced by Aflatoxin B₁ in the Rat (Meeting Abstract). (Eng) Franco, D. (Groupe de Recherche de Chirurgie hépatique, INSERM U17, Villejuif, France); Morin, J.; Torras, P.; Szekely, A. M.; Bismuth, H. *Digestion* 18(5/6): 425; 1978 (no refs)

79-5035 Transplantable Ileal Adenocarcinomas of ACI Rats. (Eng) Mori, H. (Dept. Pathology, Gifu Univ. Sch. Medicine, 40 Tsukasa-machi, Gifu 500, Japan); Tanaka, T.; Ushimaru, Y.; Kato, K.; Kawai, T.; Takahashi, M.; Hirono, I. *Gann* 70(3): 371-378; 1979.

Nine types of bracken-induced ileal adenocarcinomas were transplanted sc in ACI rats, and two of these were successfully established as transplantable tumor strains (designated 73-357 and 77-238). Ascitic conversion was successful in strain 73-357 only. Histological and electron microscopic findings are presented for the two tumor strains, which are the first transplantable ileal tumors to be described. (17 refs)

79-5036 Irreversibility of Degraded Carrageenan-induced Colorectal Squamous Metaplasia in Rats. (Eng) Oohashi, Y. (First Dept. Pathology, Sch. Medicine, Juntendo Univ., Hongo 2-1-1, Bunkyo-ku, Tokyo 113, Japan); Kitamura, S.; Wakabayashi, K.; Kuwabara, N.; Fukuda, Y. *Gann* 70(3): 391-392; 1979.

Male Sprague-Dawley rats fed a diet containing 10% degraded carrageenan (CG) for 1 day to 12 wk developed superficial hemorrhagic erosions and epithelial degeneration at the anorectal junction within 24 hr and squamous metaplasia of the rectal mucosa within 2 wk. The extent of involvement increased with the duration of CG administration. Colorectal metaplasia induced by 4-12 wk of CG feeding was still present upon examination of the rats 27 wk after the initial feeding, suggesting that irreversible squamous metaplasia is a precursor of the squamous cell carcinoma seen in laboratory animals with prolonged feeding of degraded CG. 79-5037 A Molecular Orbital Study on the Chemical Reactivity and Biological Activity of Polycyclic Aromatic Hydrocarbon Diol-Epoxides in Connection with Bay Region Theory. (Eng) Imamura, A. (Dept. Chemistry, Shiga Univ. Medical Science, Setatsukinowacho, Otsu, Shiga-ken 520-21, Japan); Koda, M.; Kato, S. *Gann* 70(3): 291-296; 1979.

A molecular orbital method was applied to several polycyclic aromatic hydrocarbon diol-epoxides to study the role of the bay region in their biological activity and chemical reactivity. Electronic structures of naphthalene, anthracene, phenanthrene, and benzo(a)pyrene diol-epoxides were calculated by a combination of the CNDO/2 (complete neglect of differential overlap) and energy minimization methods. With these methods, the most stable molecular geometry was obtained automatically. By comparing the total energy of phenanthrene diol-epoxide with that of anthracene diol-epoxide, the role of the bay region was studied in connection with chemical reactivity. It was concluded that the bay region plays an important

role when the diol-epoxide reacts with a component of the biological system via an SN1 mechanism. Moreover, benzo(a)pyrene diol-epoxide was shown to be very reactive because it contained a bay region and because of its large size. When reaction proceeded via an SN2 mechanism, the bay region had little effect on the chemical reactivity of the molecules. (21 refs)

79-5038 Quantum Chemical Studies of the Metabolism of Polycyclic Aromatic Amines and the Stabilities and Electrophilicities of Their Arylnitrenium Ions in Relation to Their Mutagenic/Carcinogenic Potencies. (Eng) Loew, G. H. (Molecular Theory Lab., Dept. Genetics, Stanford Univ. Medical Center, Stanford, CA 94305); Phillips, J.; Pack, G. *Cancer Biochem Biophys* 3(3): 101-110; 1979.

Electronic parameters related to the cytochrome P450-catalyzed reactions of eight polycyclic aromatic amines were calculated using all valence electron semiempirical molecular orbital methods. Parameters were calculated related to the relative ease of metabolic transformation of each parent compound to hydroxylamines by cytochrome P-450 and to other competing metabolic products involving ring epoxidation and hydroxylations. The eight compounds studied were 2-amino naphthalene, 1-amino naphthalene, 2-amino fluorene, 4-amino fluorene, 2-amino anthracene, 1-amino anthracene, 1-amino pyrene, and 6-amino chrysene. The calculations indicated that as the size of the ring system increases, the aryl nitrenium ions become more stable relative to the N-hydroxylamines and their esters, with the possible exception of 1-N-hydroxynaphthylamine which is predicted to form a more stable nitrenium ion than the aminofluorenes. For the four pairs of compounds studied, the parent compound which was predicted to form more hydroxylamine is the more potent mutagen and carcinogen. Considering competing ring metabolite formation, the less potent isomer has the ring carbon which is most reactive to direct phenol formation. Thus, direct phenol formation appears to be an effective detoxification pathway. Ring epoxidation, however, appears to be more activating than detoxifying. The results verify that hydroxylamine formation and the electrophilicity of aryl nitrenium ions are important steps in determining relative mutagenic activity of polycyclic aromatic amines and lead to calculated parameters which can monitor these steps and predict relative activity. (44 refs)

79-5039 Cimetidine and Gastric Cancer (Letter to Editor). (Eng) Roe, F. J. (4 Kings Road, Wimbledon SW19 8QN, England). *Lancet* 1(8124): 1039; 1979.

A long-term study in rats showed no increased risk of gastric malignancy due to cimetidine (Tagamet), which was administered at doses >60 times those used clinically. Of

the three reported cases of gastric cancer in cimetidine users, the interval from first exposure to diagnosis ranged from 10 wk to 11 mo. Thus, a causative link is highly improbable. (4 refs)

79-5040 Gastric Cancer in Patients Who Have Taken Cimetidine (5 Letters to Editor). (Eng) Rudell, W. S. (Dept. Medicine, St. James's Hosp., Leeds LS9 7TF, England); Reed, P. I.; Cassell, P. G.; Walters, C. L.; Hill, M. J.; Taylor, T. V.; Lee, D.; Howatson, A. G.; Anderson, J.; MacLeod, I. B.; Rubin, P. *Lancet* 1(8128): 1234-1236; 1979.

Several letters were written in response to a recent article stating that there was an association between cimetidine therapy and gastric cancer in three patients. The occurrence of gastric cancer in three additional patients on long-term cimetidine therapy for duodenal and/or gastric ulcer is reported. It is suggested that cimetidine may both mask the symptoms of gastric cancer and contribute to its development. However, it is only one of many drugs and dietary factors that are potentially nitrosatable under gastric conditions, and there is no good reason for singling out cimetidine as a unique hazard. The fact that the latency period between onset of treatment and diagnosis of carcinoma in the three original patients was only 6-12 mo suggests that these cancers were not in fact due to cimetidine. Furthermore, it is not known whether these patients had neoplastic changes before cimetidine treatment. (11 refs)

79-5041 The Carcinogenic Effect of TPA (12-O-Tetradecanoylphorbol-13-Acetate) When Applied to the Skin of Hairless Mice. (Eng) Iversen, U. M. (Inst. Pathology, Univ. Oslo, Rikshospitalet, Oslo 1, Norway); Iversen, O. H. *Virchows Arch [Cell Pathol]* 30(1): 33-42; 1979.

The carcinogenic effect of topical 12-O-tetradecanoylphorbol-13-acetate (TPA) was studied in hairless mice given 1, 2, 5, or 50 applications of 20 nanomoles (nmoles) of TPA and observed for 83 wk. In mice receiving 20 nmoles of TPA, one squamous cell carcinoma and one angiosarcoma of the spleen were detected, both in females. In the group painted twice with TPA there were three skin tumors (2 females, 1 male), one sarcoma of the dermis (female), and one sc myxosarcoma (female). Four skin tumors appeared in males and one in a female of the group painted five times. Three male mice had sarcomas of the dermis, and in female mice there were two benign angiomas of the liver, two granulosa cell tumors, and one thecoma of the ovaries. In the group painted 50 times, there were four skin tumors in male mice and three in females. One male and three females developed squamous cell carcinomas. One male had a malignant hepatoma, one a myxosarcoma in the abdominal cavity, and one an angiosarcoma of the thyroid. Two females had angiosarcomas of the spleen and soft tissues and one an adenocarcinoma in the omentum.

Reticuloses, which are common in hairless mice, were seen in each treatment group. The yield of skin carcinomas (4/19) in the group given 50 applications was significantly greater than in mice given ≤ 5 applications. This increase in response with dose is evidence for the carcinogenic activity of TPA. The compound should be regarded as a complete carcinogen. (18 refs)

- 79-5042 Erythroleukemia in a Renal Transplant Recipient. (Eng) Ellerton, J. A. (Dept. Medical Oncology, New England Medical Center, 171 Harrison Ave., Boston, MA 02111); deVeber, G. A.; Baker, M. A. *Cancer* 43(5): 1924-1926; 1979.

A case of erythroleukemia (EL) in a renal transplant recipient receiving long-term azathioprine therapy is reported. A 53-yr-old man developed acute EL 3 yr after renal transplantation. He had received 3 yr of immunosuppressive therapy with azathioprine (3 mg/kg/day). A preleukemic phase associated with chromosome abnormalities (consistent deletion of B-5; deletion of E-17 or a D group chromosome) was recognized. Repeat cytogenetic studies 4 mo later revealed the same B group deletion plus a G group deletion and duplication of the short arm of E-17. Azathioprine has been associated with chromosome abnormalities. Chronic stimulation of an abnormal erythroid clone by the transplantation may have hastened the development of EL. (20 refs)

- 79-5043 Chloramphenicol and Chromosomal Morphology. (Eng) Goh, K. (Univ. Rochester and Monroe Community Hosp., Rochester, NY 14603). *J Med Clin Exp Theor* 10(3): 159-166; 1979.

The effect of chloramphenicol (CM) on the chromosomes of cultured peripheral blood lymphocytes from two normal donors was studied. Ten 10-ml cultures were made from each donor. A dose of 800 μ g CM was added to two phytohemagglutinin-stimulated WBC cultures from each donor at the various stages of the cell cycle. The cultures were terminated for chromosome analyses. More abnormalities were seen in the CM-treated cultures than in the control cultures (treated with solvent alone). The highest incidence was seen when CM was added at G₀, the lowest incidence when CM was added at G₂. These results correlate well with the percentage of protein synthesis and transport to the acidic residual chromosomal protein fraction previously determined in HeLa S-3 cells. It is concluded that CM is capable of inhibiting protein synthesis, which results in a chromosome protein deficiency. This deficiency produces a "weakness" in the chromosome backbone. (14 refs)

- 79-5044 Binding of Polycyclic Aromatic Hydrocarbons to DNA of Cells in Culture: A Rapid Method for Its Analysis Using Hydroxylapatite Column Chromatography. (Eng) Shoyab, M. (Meloy Labs., Inc., 6715 Electronic Drive, Springfield, VA 22151). *Chem Biol Interact* 25(1): 71-85; 1979.

A rapid procedure to study the interaction of carcinogens with DNA in cultured cells has been developed. The cells, which are labeled with 7,12-³H]dimethylbenz[a]anthracene (³H]DMBA), are lysed with 0.24 M phosphate buffer (pH 6.8), 1% sodium dodecyl sulfate (SDS), 8 M urea and 0.01 M ethylenediamine-tetraacetate (EDTA) and sonicated. The cell lysates are fractionated on columns of hydroxylapatite. Proteins and RNA are removed with 8 M urea in 0.24 M phosphate buffer (pH 6.8). DMBA-bound DNA is eluted with 0.4 M phosphate buffer (pH 6.8). DMBA-DNA isolated by this procedure is virtually free from proteins and RNA. Thermal stability, ultraviolet spectra and the density of DNA are not altered by DMBA binding. The uptake of DMBA by mouse epidermal cells is rapid, and the binding of DMBA to DNA is linear for the first 8 hr of exposure. DMBA binds to DNA in all phases of the cell cycle. However, the highest binding occurs immediately following maximum DNA synthesis. (26 refs)

- 79-5045 Non-immunological Regression of Dimethylbenz(a)anthracene-induced Experimental Keratoacanthomas in the Rabbit. (Eng) Ramselaar, C. G. (Dept. Dermatology, St. Antonius Hosp., Jan van Seorelstraat 2, Utrecht, Netherlands); van der Meer, J. B. *Dermatologica* 158(2): 142-151; 1979.

Immunofluorescence studies and skin tests with autologous tumor extracts were performed in New Zealand white rabbits to determine the possible immune-mediated factors involved in the spontaneous regression of keratoacanthomas induced by 7,12-dimethylbenz(a)anthracene (DMBA). These tumors grow rapidly, reaching max size in a few weeks, and they resolve spontaneously without treatment. Nine rabbits were shaved weekly and the shaved area was pencilled with a 1% soln of DMBA in lanolin with 3% soft paraffin. Pencilling was stopped when a rabbit showed the first tumor: after 10-15 wk, all nine experimental rabbits had tumors (total, 17). Nine rabbits served as controls. Immunofluorescence studies revealed that there were no specific staining patterns in any of the 17 keratoacanthomas. No tumor-specific antibodies were detected. There were no immediate or delayed cutaneous hypersensitivity reactions to injections of tumor extract and normal rabbit skin. The results of this study do not implicate the immune system in keratoacanthoma regression. (26 refs)

- 79-5046 Effects of LS 1727, a Nitrosocarbamate of 19-Nortestosterone, on Dimethylbenz(a)anthracene-induced Mammary Tumors in the Rat. (Eng) Bouveng, R. (Research Labs., AB Leo, S-251 00 Helsingborg, Sweden); Ellman, M.; Gunnarsson, P. O.; Jensen, G.; Liljekvist, J.; Muntzing, J. *Eur J Cancer* 15(4): 407-414; 1979.

The effect of LS 1727, a nitrosocarbamate of 19-nortestosterone, on mammary tumors induced by dimethylbenz(a)anthracene (DMBA) was studied in virgin female Sprague-Dawley rats. Fifty-day-old animals were given 20 mg DMBA po and 7 wk later were examined for tumors. Animals with 1-5 tumors, at least one of which was >10 mm diameter, were studied. The rats were injected with LS 1727 (0.31, 1.25, 10, 20, or 40 mg/kg ip 1x/day for 4 wk) and the tumors measured for 4 wk following the treatment period. LS 1727 caused a dose-dependent reduction in tumor growth. Even at the 0.31 mg/kg dose the effect was significant. Neither 19-nortestosterone nor 1-(2-chloroethyl)-3-cyclohexyl-nitrosourea (CCNU), a compound with structural similarity to the alkylating moiety of LS 1727, had any significant effect on tumor growth. LS 1727 administration reduced the uptake of radioactivity in the tumors after injection of (³H) dihydrotestosterone but not after injection of (³H) estradiol-17 β or (³H) progesterone. There was no accumulation of radioactivity in the tumors after injection of (³H)-LS 1727. Thin layer chromatography revealed that LS 1727 is rapidly metabolized (<30 min) to 19-nortestosterone and polar metabolites. These results show that LS 1727 has a growth-inhibitory effect, probably exerted by both an alkylating and a hormonal action of the compound, on DMBA-induced mammary tumors. (23 refs)

- 79-5047 Prolactin Receptors in Primary Cultures of Carcinogen-induced Rat-Mammary Tumors. (Eng) Costlow, M. E. (Dept. Biochemistry, St. Jude Children's Res. Hosp., 332 N. Lauderdale, Memphis, TN 38101); Gallagher, P. E.; Koseki, Y. *Mol Cell Endocrinol* 14(1): 81-97; 1979.

Some of the conditions, including those for tumor cell dissociation, that influence the growth of mammary tumor cells and the concentration of prolactin (PRL) binding sites in vitro are presented. 7,12-Dimethylbenz(a)anthracene-induced Sprague-Dawley rat mammary tumors were dissociated with collagenase and hyaluronidase and placed into primary culture. In most cultures, specific binding of ¹²⁵I-labeled ovine PRL was (1) lower than that for the original tumors unless bovine PRL (1 μ g/ml) had been added to the dissociation medium and (2) varied with the type of growth medium used. The level of PRL binding in cultured cell homogenates was relatively constant for the first 7-10 days. PRL binding in cultured cell homogenates was max at pH 7.0, proportional to cell protein, specific for PRL, and reached a steady state by 12 hr at 22 C. The

half-max inhibition of ¹²⁵I-labeled PRL binding by unlabeled PRL was 100 nanograms(ng)/ml for cells grown in 5-1,000 ng PRL/ml. After PRL was removed from the growth medium, the level of available binding sites progressively increased, reached a max at 48 hr, and then declined. At 48 hr, the dissociation constant for PRL binding (Kd approx 1×10^{-10} M) was comparable to that in the tumors. In some cultured tumors, a 48-hr treatment with 0.5 or 1.0 ng PRL/ml increased the level of PRL binding. PRL increased DNA synthesis, and its removal reduced [³H] estradiol and [³H] R5020 binding to cultured cell cytosols. (32 refs)

- 79-5048 Studies on the Formation of Lipophilic Derivatives of the Chemical Carcinogen 7,12-Dimethylbenz(a)anthracene In Vivo. (Eng) Khanduja, K. L. (Dept. Biophysics, Postgraduate Inst. Med. Educ. Res., Chandigarh, India). *Bull Postgrad Inst Med Educ Res Chandigarh* 12(3): 144-149; 1978.

The composition and the amount of lipophilic derivatives of 7,12-dimethylbenz(a)anthracene (DMBA, 2 mg, iv) in various organs was studied using virgin female Wistar rats. In all organs except the mammary gland, radioactivity associated with ³H-DMBA was maximal at 5 min. DMBA continued to accumulate in the mammary gland for 1.5 hr. The concentrations decreased rapidly with time in the liver, kidney, spleen, and blood. Liver lipid elution profiles revealed the presence of two peaks. Similar peaks were observed with the splenic lipids. The concentration in kidney lipids was low and no significant concentration of slowly excreting derivatives in the mammary gland was observed. Further investigations are required in order to understand the role of these derivatives in DMBA-induced mammary gland carcinogenesis. (10 refs)

- 79-5049 The Effect of Hydroxylamine on the Morphology of the Rat Mammary Gland and on the Induction of Mammary Tumors by 7,12-Dimethylbenz(a)anthracene. (Eng) Poukka-Evarts, R. (Lab. Carcinogen Metabolism, Div. Cancer Cause and Prevention, NCI, Bethesda, MD 20205); Brown, C. A.; Atta, G. J. *Exp Mol Pathol* 30(3): 337-348; 1979.

The effect of hydroxylamine (HA) on the morphology of rat mammary gland and on the formation of mammary tumors induced by 7,12-dimethylbenz(a)anthracene (DMBA) was studied in virgin female Sprague-Dawley rats. The rats were divided into five groups and were given HA sulfate in drinking water as a 10 mM soln, (Group 2), or 11 mg DMBA in corn oil po through a stomach tube, (Group 5). Groups 3 and 4 received a combination of HA and DMBA. Groups 1 (control) and 5 received tap water throughout the experiment. Tumors first appeared 18 days after DMBA administration among Group 3 rats who had received HA for 14 days prior to DMBA administration.

Among animals in Group 4, where HA administration was started 2 wk after DMBA administration the first palpable tumors appeared at the same time as among DMBA only treated animals (Group 5). The mean latency period, 102.4 days, for Group 4, which was given HA after DMBA, was significantly greater than the latency periods of 63.1 days for group 3, given HA before DMBA, and 62.9 days for Group 5, the DMBA only group. The incidence of tumors at the end of the experiment did not differ significantly. HA caused excessive growth and secretory activity in the mammary gland. Atrophic changes were evident among DMBA treated animals 19 days after DMBA administration. By 5 wk after carcinogen administration the lobules had mostly disappeared. The mammary glands of the rat which received HA for 14 days before DMBA were partially protected against the DMBA induced destruction and contained some areas where the lobules were well preserved. A delayed effect of DMBA treatment was the formation of dark-staining irregular structures which originated either from the larger ducts or from the duct terminals and which were morphologically different from hyperplastic alveolar nodules. (19 refs)

79-5050 Infertility in Mice Following Prenatal Exposure to 9,10-Dimethyl-1,2-benzanthracene (DMBA) (Meeting Abstract). (Eng) MacKenzie, K. M. (Raltech Scientific Services, Incorporated, Madison, WI); Lucier, G. W. *Biol Reprod* 20(Suppl 1): 30A; 1979 (no refs)

79-5051 Effect of Ovariectomy, Adrenalectomy and Hypophysectomy on Carcinogenesis of the Endometrium by 7,12-Dimethylbenz[a]anthracene in Rats. (Eng) Sekiya, S. (Dept. Obstetrics and Gynecology, Chiba Univ. Sch. Medicine, Inohana 1-8-1, Chiba 280, Japan); Kikuchi, Y.; Katoh, T.; Kobayashi, W.; Takeda, B.; Takamizawa, H. *Gynecol Oncol* 7(3): 281-287; 1979.

The effects of ovariectomy (ovx), adrenalectomy (adx), or hypophysectomy (hypox) (performed at 5 wk of age) on endometrial carcinogenesis induced by 7,12-dimethylbenz(a)anthracene (DMBA)-impregnated sutures applied to the endometrial cavity were studied using female Sprague-Dawley rats. At 6 wk after DMBA treatment, squamous metaplasia of the endometrial epithelium was frequently found in all but hypox rats. At 12 wk, hyperplasia of squamous-type cells was observed in 2/7 unoperated controls, 1/3 adx rats, and 1/4 ovx rats. At 24 wk, adenocarcinomas were found in 2/10 controls; squamous cell carcinomas were found in 3/10 controls and 1/4 adx rats; and sarcoma was observed in 1/6 ovx rats. No endometrial hyperplasia or carcinoma was observed in any hypox rat. Serum estrone and estradiol values were lower in ovx and hypox rats at 12 and 24 wk than in control and adx rats ($p < 0.02$). Serum progesterone levels were 7.2, 10.3,

2.0, and 0.4 nanograms/ml in the control, adx, ovx, and hypox rats, respectively. The results suggest that endogenous estrogen may play an essential role in chemically-induced endometrial carcinogenesis. (16 refs)

79-5052 Influence of Surface Lipids on Skin Carcinogenesis in Rats. (Eng) Arffmann, E. (Dept. Pathology, Aalborg Hosp. North, P.O. Box 561, DK-9100 Aalborg, Denmark); Hjerne, N. *Acta Pathol Microbiol Scand [A]* 87(3): 143-149; 1979.

The effect of skin-surface lipid extraction (SSLE) on skin carcinogenesis by various carcinogenic hydrocarbons was studied using female Wistar specific-pathogen-free rats. The rats, some of which had undergone SSLE, received 20 topical applications of hydrocarbon at 2-wk intervals. Dibenz(a,h)anthracene (DBA) induced a basalioma in 1/20 rats. 3-Methylcholanthrene (MCA) induced basaliomas in 14/20 rats and a pure squamous cell carcinoma in 1/20. 7,12-Dimethylbenz(a)anthracene (DMBA) induced advanced squamous cell carcinomas, often keratinizing, in 12/20 animals, papillomas in 3/20, and skin sarcomas in 2/20. Benzo(a)pyrene (BP) induced squamous cell tumors with cellular atypia in 8/20 rats, basaliomas in 4/20, and a benign squamous cell papilloma in 1/20. SSLE had no significant effect on tumor type but did increase the latency period and decrease the rate of tumor development in BP- and MCA-treated animals. In contrast, SSLE enhanced the rate of tumor production by DMBA and reduced the latency period. Malignant tumors in sites other than the skin were rarely seen and only in animals treated with DMBA. (17 refs)

79-5053 Differential Susceptibility of the Axilla and Groin of the Mouse to Chemical Oncogenesis. (Eng) Prehn, R. T. (Jackson Lab., Bar Harbor, ME 04609); Karnik, V. *Nature* 279(5712): 431-433; 1979.

The induction of sc sarcomas in the axillary and inguinal regions of female BALB/cByJ and (C57BL/6JN1cr x BALB/cAnN1cr)F₁ mice by implantation of 3-methylcholanthrene (MC)-impregnated wafers was studied. When the concentration of MC in the disks was $\geq 0.5\%$, tumors usually appeared first by the axillary disks. This tendency diminished as the MC concentration was reduced, disappearing at a concentration of 0.01%. Axillary preference also appeared to persist in irradiated-thymectomized mice treated with sc MC. The possibility that the preference was in some way related to immunologic phenomena cannot be discarded, but most of the effect of MC concentration was probably mediated by some nonimmunologic gradient, the effect of which may have been magnified by an altered immune response. - 79-5054 Tumour-related Antigen Specificities Associated with 3-Methylcholanthrene-treated Rat Embryo Cells. (Eng) Embleton, M. J. (Cancer Res. Campaign Labs., Univ. Nottingham, Nottingham NG7 2RD, England); Baldwin, R. W. *Int J Cancer* 23(6): 840-845; 1979.

Male inbred WAB/Not rats were immunized with syngeneic embryo cells treated in vitro for 18 hr with 10 μ g/ml 3-methylcholanthrene. (3-MC), and their sera were screened for membrane immunofluorescence reactivity against panels of established chemically induced syngeneic rat tumors. Three separate antiserum pools raised against 3-MC-treated cells reacted with certain chemically induced tumors, whereas antisera to control (dimethyl sulfoxide-treated) cells were completely negative. The reactions observed were reproducible and highly specific for particular target tumors. Absorption studies indicated that each antiserum contained antibodies to several different antigens present on different tumors. Antiserum prepared against extranuclear membranes from 3-MC-treated cells, rather than intact 3-MC-treated cells, was negative. This suggests that the antibody responses were directed against antigens arising subsequently to 3-MC treatment and injection into syngeneic hosts. It is postulated that carcinogen treatment results in the acquisition of multiple neoantigens among a treated cell population and that these neoantigens represent an early change in a sequence of events leading to malignant transformation. - 79-5055 Application of Mass Spectrometry to the Analysis of Polycyclic Aromatic Hydrocarbons and Related Compounds in the Environment. (Eng) Sakuma, T. (York Univ., Toronto, Canada). *Diss Abstr Int [B]* 39(11): 5345-5346; 1979 (no refs)

- 79-5056 Optimization of a Fluorimetric Group Detection Method for Polycyclic Aromatic Hydrocarbons on Silica Gel. (Ger) Hellmann, H. (Albert-Schweitzer-Strasse 9, D-5400 Koblenz, W. Germany). *Fresenius Z Anal Chem* 295(5): 388-392; 1979.

An improved fluorimetric method for the detection and determination of six polycyclic aromatic hydrocarbons (fluoranthene, 3,4-benzofluoranthene, 11,12-benzofluoranthene, 3,4-benzopyrene, 1,12-benzperylene, and indeno[1,2,3-cd]pyrene) in drinking water is described. The detection limit of the individual compounds is <0.1 nanogram. (4 refs)

- 79-5057 Xenobiotics and Chemical Carcinogens Induced Acceleration of Microsomal DNA Synthesis. (Rus) Lerman, M. I. (Inst. Biological and Medical Chemistry, Moscow, USSR); Abakumova, O. Iu.;

Kutsenko, N. G.; Podobed, O. V. *Biokhimiia* 44(4): 699-704; 1979.

The hypothesis that the metabolism of microsomal DNA (msDNA) is associated with the xenobiotic system and that typical inducers of this system can affect the synthesis, repair, and degradation of msDNA was tested. C3HA mice (intact or with ascitic hepatoma 22A) were inoculated with phenobarbital (PB: 60 mg/kg), benzo(a)pyrene (BP: 20 mg/kg), methylnitrosourea (MNU: 30 mg/kg), the protein synthesis inhibitors cycloheximide (CH: 0.25 mg/kg) or puromycin (PM: 0.6 mg/kg), and the DNA repair inhibitors hydroxyurea (HU: 2.5 g/kg) or caffeine (2.5 mg/kg). Administration of BP, MNU, and PB to tumor-free mice resulted in a rapid and marked increase of ¹⁴C-thymidine incorporation into msDNA in the liver, but the msDNA synthesis system in the liver of mice with hepatoma 22A was resistant to MNU, CH, and PM. - 79-5059 The Use of the *Salmonella*/Microsomal Assay to Determine Mutagenicity in Paired Chemical Mixtures. (Eng) Salamone, M. F. (Centre Res. Environmental Quality, York Univ., 4700 Keele St., Downsview (Toronto), Ontario M3J 2R3, Canada); Heddle, J. A.; Katz, M. *Can J Genet Cytol* 21(1): 101-107; 1979.

The mutagenicities of two sets of chemicals acting singly and in pairwise combinations were studied in the *Salmonella*/microsomal assay. The first set consisted of the promutagens benzo(a)pyrene (BP) and benzo(rst)pentaphene [B(rst)P]. The second set contained the direct-acting mutagens methylnitronitrosoguanidine (MNNG) and ethyl methanesulfonate (EMS). In the tests with BP and B(rst)P, the quantities of S-9 mix ranged from 0.05 to 1.0 ml with increasing concentrations of each chemical. At any one chemical concentration, there was a quantity of S-9 that produced a max number of revertant colonies in *S. typhimurium* TA98 or TA100. Excess quantities of the mix partially or totally inhibited the mutagenicity of BP or B(rst)P. No additive mutagenic effects were observed when the two chemicals were tested in combination. MNNG or EMS, when tested individually without the S-9 mix, produced almost linear responses with increasing concentration. In combination, these chemicals also showed linear responses that closely approximated the theoretical additivity, indicating that the mutagenicity of the mixtures was the sum of the activities of each component. (12 refs)

79-5060 Biological Activity of Benzo[*a*]pyrene. An Assessment Based on Mutagenic Activities and Metabolic Profiles of the Polycyclic Hydrocarbon and its Derivatives. (Eng) Wood, A. W. (Dept. Biochemistry and Drug Metabolism, Hoffmann-La Roche Inc., Nutley, NJ 07110); Levin, W.; Thakker, D. R.; Yagi, H.; Chang, R. L.; Ryan, D. E.; Thomas, P. E.; Dansette, P. M.; Whittaker, N.; Turujman, S.; Lehr, R. E.; Kumar, S.; Jerina, D. M.; Conney, A. H. *J Biol Chem* 254(11): 4408-4415; 1979.

The mutagenic activity of benzo(e)pyrene (BeP) and six of its derivatives was studied in the absence and presence of a cytochrome P-450-dependent monooxygenase system. In the presence of hepatic microsomes from Aroclor 1254-pretreated rats or the cytochrome P-450-dependent monooxygenase system purified to near homogeneity for these microsomes, BeP, *trans*-9,10-dihydroxy-9,10-dihydro-BeP (bay region dihydrodiol) and *trans*-9,10-dihydroxy-9,10,11,12-tetrahydro-BeP were metabolized to products which had little or no mutagenic activity toward strains TA98 and TA100 of *Salmonella typhimurium*; products formed from *trans*-4,5-dihydroxy-4,5-dihydro-BeP (K-region dihydrodiol) had modest mutagenic activity; and products from 9,10-dihydro-BeP were 10- to 25-fold more active than those from BeP. The high intrinsic mutagenic activity of the chemically synthesized benzo ring tetrahydroepoxide of 9,10-dihydro-BeP in both strains of bacteria and in cultured Chinese hamster V79 cells suggested that the high mutagenicity of 9,10-dihydro-(BeP) after metabolism was mediated by this bay region tetrahydroepoxide. Liver microsomal metabolites of several of the BeP derivatives were analyzed by high pressure liquid chromatography. Results indicated that lack of formation of a benzo ring epoxide from 9,10-dihydroxy-9,10-dihydro-BeP may explain its inability to be metabolically activated by rat liver enzymes to mutagenic products and may contribute to the low carcinogenic activity of benzo(e)pyrene in rodents. (42 refs)

79-5061 Comparative Studies on the Covalent Binding of the Carcinogen Benzo(a)pyrene to DNA in Various Model Systems. (Eng) Jaggi, W. (Inst. Toxicology, Federal Inst. Technology, Univ. Zurich, CH-8603 Schwerzenbach, Switzerland); Lutz, W. K.; Schlatter, C. *Experientia* 35(5): 631-632; 1979.

The covalent binding of tritiated benzo(a)pyrene (BP) was studied in rat liver in vivo, rat liver perfused in situ, single liver cells, liver homogenate, liver microsomes, fibroblasts from a rat granuloma pouch, and cells from rabbit cornea and monkey kidney cell lines. The binding of BP per mg of single liver cell DNA showed remarkably little variability and high specificity. The single cell system represented a valuable compromise between the in vivo system and the microsomal incubation with respect to sensitivity, reproducibility, and biological relevance. The various

model systems differed by a factor of approx 30 with respect to the limit of detection, the single liver cells being only five-fold less sensitive than the microsomal system. Preference would generally be given to the in vivo system, but single liver cells would be recommended if the amount of available radioactivity were a limiting factor, and the liver microsomal system would be recommended for structural analyses of DNA-bound compounds. (12 refs)

79-5062 The In Vitro Metabolism and Covalent Binding of Benzo[*a*]pyrene to DNA Catalysed by Trout Liver Microsomes. (Eng) Ahokas, J. T. (Clinical Pharmacology Unit, Dept. Medicine, Princess Alexandra Hosp., Ipswich Road, Brisbane, Queensland 4102, Australia); Saarni, H.; Nebert, D. W.; Pelkonen, O. *Chem Biol Interact* 25(1): 103-111; 1979.

The production of reactive intermediates of benzo(a)pyrene (BP) by trout (*Salmo trutta lacustris*), roach (*Rutilus rutilus*), and rat (male Sprague-Dawley) liver microsomes was studied. The binding of BP metabolites to DNA catalyzed by trout liver microsomes was three- to fourfold higher than that catalyzed by rat liver microsomes, although pretreatment of the rats with 3-methylcholanthrene (MC, 25 mg/kg, ip) increased DNA binding thirtyfold. Roach liver microsomes were very inefficient in catalyzing BP binding to DNA. The major nucleoside-metabolite complexes formed by trout and rat liver microsomes from BP were nucleoside adducts of the BP-7,8-diol-9,10-epoxides and the adduct of 9-OH-BP-4,5-oxide. Other products produced by the trout microsomes were the nucleoside adduct of BP-4,5-oxide and nucleoside adducts of BP quinones and/or BP-7,8-oxide. Very little BP-4,5-dihydrodiol was produced by the trout liver microsomes. (36 refs)

79-5063 Formation of Benzo(a)pyrene Metabolite-Nucleoside Adducts in Isolated Perfused Rat and Mouse Liver and in Mouse Lung Slices. (Eng) Kahl, G. F. (Dept. Pharmacology, Univ. Mainz, Mainz, W. Germany); Klaus, E.; Legraverend, C.; Nebert, D. W.; Pelkonen, O. *Biochem Pharmacol* 28(7): 1051-1056; 1979.

The formation of DNA- and RNA-containing adducts with benzo(a)pyrene (BP) metabolites in perfused livers from rats and from mice that are genetically responsive to inducers of cytochrome P₁-450 is described, along with the formation of adducts in lung slices from these mice. The adducts were identified by Sephadex LH20 chromatography. In livers from β -naphthoflavone-pretreated Sprague-Dawley rats, four different deoxyribonucleoside complexes were observed. These were tentatively attributed to DNA modification by the 7,8-diol-9,10-epoxide(s), secondary metabolites of BP quinones, the 4,5-oxide, and secondary metabolites of BP phenols. The diol epoxide-deoxyribo-

nucleoside adducts were also detected in perfused liver and in lung slices from 3-methylcholanthrene-treated genetically responsive C57BL/6N mice, but no adducts were detectable in similar samples from 3-methylcholanthrene-treated genetically nonresponsive DBA/2N mice. In the perfused liver of phenobarbital-pretreated rats, the 4,5-oxide-deoxyribonucleoside adduct was present. These results suggest that some of the BP metabolite-nucleoside complexes generated by microsomes and deproteinized DNA *in vitro* also occur in intact rodent liver and lung tissues. Furthermore, complexes with the diol epoxide(s) were observed with RNA from the perfused liver of β -naphthoflavone-treated, but not from untreated or phenobarbital-treated, rats. Complexes between ribonucleoside(s) and the diol epoxide(s) were also found in perfused liver or lung slices from genetically responsive, but not from genetically nonresponsive mice. (37 refs)

- 79-5064 Induction of Enzyme-altered Islands in Rat Liver by a Single Treatment with Benzo(a)pyrene after Partial Hepatectomy. (Eng) Hirakawa, T. (Dept. Experimental Pathology, Cancer Inst., Kami-Ikebukuro 1-37-1, Toshima-ku, Tokyo 170, Japan); Ishikawa, T.; Nemoto, N.; Takayama, S.; Kitagawa, T. *Gann* 70(3): 393-394; 1979.

The number of enzyme-altered islands deficient in canalicular ATPase was significantly increased ($p < 0.05$) in the livers of male Sprague-Dawley rats that had received a single ip injection of benzo(a)pyrene (BP: 200 mg/kg) 24 hr following partial hepatectomy. This indicates that BP induces putative precancerous hepatic lesions following partial hepatectomy. The number of enzyme-altered islands was increased even more ($p < 0.02$ in comparison with controls) in hepatectomized, BP-treated rats that received a diet containing 0.05% phenobarbital for 10 wk. (10 refs)

- 79-5065 Binding of 6-Hydroxymethylbenzo(a)pyrene and 6-Acetoxyethylbenzo(a)pyrene to DNA. (Eng) Tay, L. K. (Dept. Pharmacology and Medicine, Univ. Kentucky Coll. Medicine, Lexington, KY 40506); Sydnor, K. L.; Flesher, J. W. *Chem Biol Interact* 25(1): 35-44; 1979.

The carcinogenic hydrocarbons 6-hydroxymethylbenzo(a)pyrene (6-HOCH₂-BP) and 6-acetoxyethylbenzo(a)pyrene (6-AcOCH₂-BP) were examined for their ability to bind to rat and calf thymus DNA. The data indicate that there are no appreciable differences in the amount of binding to the two types of DNA. Nonenzymatic binding of 6-HOCH₂-BP was low (5 μ mol hydrocarbon/mol DNA P) but 6-AcOCH₂-BP was bound to a considerable extent (88.4-97.3 μ mol hydrocarbon/mol DNA P). Nonenzymatic

binding of 6-HOCH₂-BP was greatly increased in the presence of ATP. Binding of 6-HOCH₂-BP in the presence of liver microsomes from untreated rats or from rats pretreated with 3-methylcholanthrene (3-MC) never exceeded 5 μ mol hydrocarbon/mol DNA P. Binding of 6-HOCH₂-BP in the presence of a 3'-phosphoadenosine-5'-phosphosulfate generating system was less than nonenzymatic binding mediated by ATP and was dependent on the presence of ATP rather than ATP and sulfate. Binding was reduced by 50% when ADP was employed in the nonenzymatic reaction and was negligible in the presence of AMP or adenosine, indicating that a diphosphate group is necessary. Incubation of 6-HOCH₂-BP with DNA in the presence of ATP, cytidine triphosphate, guanosine triphosphate, or uridine triphosphate showed that ATP was the most effective mediator of the binding reaction. These observations suggest that 6-HOCH₂-BP is converted to a phosphate ester which, like 6-AcOCH₂-BP, is much more reactive than 6-HOCH₂-BP itself. (18 refs)

- 79-5066 Detection of Mutagenic Polycyclic Aromatic Hydrocarbons in African Smoked Fish. (Eng) Mossanda, K. (Laboratoire d'Analyse des Denrees Alimentaires, Universite de Liege, Boulevard de la Constitution, 151, B 4020 Liege, Belgium); Poncelet, F.; Fouassin, A.; Mercier, M. *Food Cosmet Toxicol* 17(2): 141-143; 1979.

The mutagenicity of six polycyclic aromatic hydrocarbons found in African smoked fish was tested in several *Salmonella typhimurium* strains. In the presence of fortified rat liver postmitochondrial fractions, mutagenic activity was observed with o-phenylenepyrene, coronene, benzo(g,h,i)perylene, and triphenylene in the plate incorporation test, and with fluoranthene in the bacterial fluctuation test. No mutagenic effects of benzo(b)fluoranthene were detected in any of the strains. (14 refs)

- 79-5067 Mutagenicity of Coal Tar Preparations Used in the Treatment of Psoriasis. (Eng) Sapers-tein, M. D. (Anaerobic Bacteriology Res. Lab., V.A. Wadsworth Medical Center, Los Angeles, CA 90073); Wheeler, L. A. *Toxicol Lett* 3(6): 325-329; 1979.

The mutagenicity of four coal tar preparations (Zetar Emulsion, Estar, Lavatar, and Coal Tar Solution USP) used to treat psoriasis was evaluated in the Ames *Salmonella*/microsome mutagenicity test. All the tar products were mutagenic when plated with a liver homogenate and cofactors (S9 mix) on *Salmonella typhimurium* strain TA98. There was a fivefold difference in the mutagenicities of these products when they were compared on the basis of his⁺ revertants per microgram of tar. Zetar Emulsion, which contains whole coal tar, was more mutagenic than

the other preparations, which contain selective extracts or distillates of coal tar. This suggests that some of the processed coal tars used in various psoriasis medications may be less mutagenic than crude coal tar itself. (9 refs)

- 79-5068 The Metabolism of Dieldrin and Two of Its Analogues: The Relationship Between Rates of Microsomal Metabolism and Rates of Excretion of Metabolites in the Male Rat. (Eng) Chipman, J. K. (Dept. Physiology & Biochemistry, The University, Whiteknights, Reading RG6 2AJ, Berks, England); Walker, C. H. *Biochem Pharmacol* 28(8): 1337-1345; 1979.

The hepatic microsomal metabolism rate of dieldrin and two of its analogs, 1,2,3,4,9,9-hexachloro-1,4,4a,5,6,7,8,8a-octahydro-*exo*-7,8,-epoxy-1,4-methanonaphthalene (HCE) and 1,2,3,4,9,9-hexachloro-1,4,4a,5,6,7,8,8a-octahydro-6,7-epoxy-1,4-methanonaphthalene (HEOM), was compared with the rate of excretion of their metabolites. Male Wistar rats fitted with reentrant bile duct cannulas were given [^{14}C]-dieldrin, [^{14}C]-HCE, and [^{14}C]-HEOM (15 mg/kg of each) by ip injection. Bile collections were made without anesthesia, and nearly all ^{14}C excretion occurred by this route. ^{14}C excretion rates were max between 20 and 40 min after dosing, and they were much lower for dieldrin [3.17 nanomoles (nmol)/kg/min] than for HCE or HEOM (204 and 298 nmol/kg/min, respectively). Induction of liver enzymes by treatment with sodium phenobarbitone significantly increased ^{14}C excretion with dieldrin (threefold) but not with HCE. For each compound, the rates of ^{14}C excretion in vivo were compared with the rates of metabolism in vitro by liver microsomes. The pattern of primary metabolism observed in vivo was similar to that found in vitro for both HCE and HEOM. Whereas HCE was metabolized predominantly by microsomal monooxygenase attack, both monooxygenase and epoxide hydratase were important in the degradation of HEOM. The microsomal metabolism of HCE and HEOM by noninduced rat liver microsomes was >100 times greater than that reported for dieldrin using induced rat liver microsomes. When values were expressed in terms of unit body wt, the max microsomal metabolism rates for HCE and HEOM were five to six times greater than the corresponding max rates of biliary excretion of their metabolites in noninduced rats. HCE concentrations were measured in liver microsomes from noninduced rats dosed with the chemical. The rates of hydroxylation by liver microsomes at these concentrations were of the same order as the corresponding rates of biliary excretion for the hydroxylated metabolites. The microsomal hydroxylation rate for HCE increased approx 17-fold in terms of liver wt, after phenobarbitone induction. These results suggest that the metabolism rate can limit the excretion rate of dieldrin metabolites in the male rat. With HCE and HEOM, however, the max metabolism rate is much faster and does not apparently influence the excretion rate. There may be a "threshold metabolic rate"

for these highly liposoluble compounds below which the excretion rate is limited by the metabolism rate. (23 refs)

- 79-5069 Carcinogenic Hydrocarbons Increase the Acceptance of Transfer Ribonucleic Acid for Methionine. (Eng) Hradec, J. (Dept. Biochemistry, Oncological Inst., 180 00 Prague 8, Czechoslovakia); Dusek, Z.; Bahna, L. *Biochem Pharmacol* 28(7): 1157-1161; 1979.

Several carcinogenic and noncarcinogenic polycyclic aromatic hydrocarbons (PAH) were preincubated with a subcellular fraction of Wistar rat liver microsomes. After this preincubation, cytosol was isolated from the mixture and tested for its ability to promote the binding of methionine to endogenous transfer RNA (tRNA). Cytosols from subcellular rat liver preparations treated with carcinogenic PAH significantly enhanced the binding of methionine to endogenous tRNA, and tRNA from the same preparations had an increased acceptance for this amino acid if it was incubated with aminoacyl-tRNA synthetases from normal rat liver or from *Escherichia coli*. Preparations pretreated with noncarcinogenic PAH did not differ from controls in these respects. The activity of methionyl-tRNA synthetase was not enhanced by any of the hydrocarbons tested. Methionyl-tRNA was not stimulated if carcinogenic PAH were added directly to the incubation mixtures containing cytosol or the aminoacyl-tRNA synthetases and tRNA. The active intermediates into which parent carcinogenic PAH are converted by microsomal enzymes apparently modify tRNA and, thus, enhance its acceptance for methionine. (28 refs)

- 79-5070 The Effects of Cortisol on Protein Metabolism and on Transfer Ribonucleic Acid Methylase Activity in Rhabdomyosarcoma of Rats. (Eng) De Loecker, W. (Afdeling Biochemie, Departement Humane Biologie, Faculteit der Geneeskunde, K.U. Leuven, Belgium); De Wever, F.; Leyman, A. M.; Doms, D. *Arch Int Pharmacodyn Ther* 238(2): 333-343; 1979.

The effects of cortisol on protein metabolism were examined in rhabdomyosarcomas experimentally induced in male albino Wistar R rats by a single im injection of 0.028 mg cobalt powder into the adductor muscle of the hind limb. In vivo treatment of tumor-bearing animals with 1 or 10 mg cortisol im resulted in a reduced incorporation of [2- ^{14}C]glycine into the tumor proteins. In vitro application of 0.01-100 μg cortisol to tumor slices equally reduced the amino acid incorporation into the proteins. These inhibitions could not be explained by modifications in protein, RNA, or DNA levels or by changes in the membrane function. Factors inhibiting the amino acid incorporation into tumor proteins could be located in the 105,000 $\times g$ supernatant protein fraction. The tumor transfer RNA methylase activity became markedly inhibited by cortisol treatment. (42 refs)

- 79-5071 The Effect of Ethylnitrosourea on the Activity of NAD-Dependent Glycero-3-Phosphate Dehydrogenase in the Fifth Nerve of Developing Rats and its Relation to Myelination and Tumor Induction. (Ger) Coutelle, R. (Zentralinstitut für Krebsforschung der AdW der DDR, Lindenberger Weg 80, DDR-1115 Berlin-Buch, E. Germany); Enke, H. *Arch Geschwulstforsch* 49(1): 6-14; 1979.

The effect of a single dose of ethylnitrosourea (ENU; 85 mg/kg sc), injected at birth, on the activity of NAD-dependent L- α -glycero-3-phosphate dehydrogenase (GPDH) in the trigeminal nerve was studied in male and female inbred albino rats between days 7 and 70 of their lives. In the untreated controls, the enzyme activity rose rapidly between days 7 and 35, after which it remained practically constant, indicative of the conclusion of the myelination process by age 35 days. In the ENU-treated rats, the enzyme activity was significantly lower, reaching the values of the 35-day-old untreated animals only at age 63 days. About 26% of the activity values of the treated animals were below the lower confidence limit of the controls. (24 refs)

- 79-5072 Differential Expression of Components of the Adenylate Cyclase System During Growth of Astrocytoma Cells in Culture. (Eng) Harden, T. K. (Dept. Pharmacology, Univ. North Carolina Sch. Medicine, Chapel Hill, NC); Foster, S. J.; Perkins, J. P. *J Biol Chem* 254(11): 4416-4422; 1979.

The amount of cyclic AMP (cAMP) that accumulates in 1321N1 astrocytoma cells in response to isoproterenol (10 μ M) or prostaglandin E₁ (PGE₁) (10 μ M) varies as a function of time of cells in culture. Under normal culture conditions isoproterenol-stimulated cAMP accumulation increased 3- to 4-fold during the first 2 days following subculture and then declined within 1 wk to the original level. In contrast, PGE₁ responsiveness increased by less than 2-fold. Changes in the responsiveness of intact cells were reflected by similar alterations in isoproterenol- and PGE₁-stimulated adenylate cyclase activity in broken cell preparations. Kinetic analysis of the cAMP degradative capacity of cells during 192 hr in culture indicated that only a small change occurred in the phosphodiesterase activity of the cells. The density of β -adrenergic receptors (moles/mg of protein or moles/cell) as measured by the specific binding of ¹²⁵I-hydroxybenzylpindolol increased markedly during the first 2 days of culture, then declined over the next 6 days. Cells cultured for 2-3 days only did not exhibit a further increase in isoproterenol responsiveness or β -receptor density upon subculture, while these increases were seen upon transfer of cells expressing less than optimal responsiveness (ie, 5- to 9-day old cells). Plating of older cells at high density ($>1 \times 10^5$ cells/cm²) also prevented increases in isoproterenol responsiveness and β -adrenergic receptor density. It is concluded that

changes in responsiveness to catecholamines during growth of astrocytoma cells in culture occur as a result of changes in the number of β -adrenergic receptors per cell, which is optimal in sparse cultures and declines as cell density increases past confluency. (23 refs)

- 79-5073 Microsomal Aryl Hydrocarbon Hydroxylase in Rat Adrenal: Regulation by ACTH but Not by Polycyclic Hydrocarbons. (Eng) Guenther, T. M. (Developmental Pharmacology Branch, Natl. Inst. Child Health and Human Development, Bethesda, MD 20014); Nebert, D. W.; Menard, R. H. *Mol Pharmacol* 15(3): 719-728; 1979.

Adrenal aryl hydrocarbon hydroxylase (AHH) activity was further characterized in Sprague-Dawley rats. Total P-450 content is >4 times greater in the rat adrenal cortex mitochondria than in microsomes, but AHH activity is >60 times higher in adrenal cortex microsomes than in mitochondria. The rat adrenal microsomal hydroxylase activity is strongly inhibited by α -naphthoflavone in vitro; progesterone 21-hydroxylase (PH) is not. In rats hypophysectomized for 30 days, AHH decreases to about 6% of control values, but PH falls to about 38% of that in sham-operated control animals. Hypophysectomy causes a striking decrease in an electrophoretic band estimated to be about 57,000 daltons. AHH specific activity and this electrophoretic band are restored to normal levels in adrenal microsomes of hypophysectomized rats that have received exogenous ACTH treatment. AHH in adrenal microsomes is not induced, however, in the hypophysectomized or intact rat by 3-methylcholanthrene or high doses of 2,3,7,8-tetrachlorodibenzo-p-dioxin. These data show that AHH and PH may be associated with different forms of adrenal microsomal P-450. It is of interest that AHH in the adrenal of the untreated rat is similar (in sensitivity to α -naphthoflavone and in the presumed association with the 57,000-dalton apoprotein subunit on electrophoresis) to polycyclic aromatic compound-induced AHH and its associated cytochrome P₁-450 in the rat liver. The regulation of the adrenal hydroxylase by the large polypeptide hormone ACTH and the lack of inducibility by polycyclic aromatic compounds, however, are characteristics distinctly different from those of the P₁-450-associated hepatic enzyme. - 79-5074 Differential Effects of Antioxidants, Steroids and other Compounds of Benzo(a)pyrene 3-Hydroxylase Activity in Various Tissues of Rat. (Eng) Rahimtula, A. D. (Dept. Biochemistry, Memorial Univ. Newfoundland, St. John's, Newfoundland, A1B 3X9 Canada); Zachariah, P. K.; O'Brien, P. J. *Br J Cancer* 40(1): 105-112; 1979.

The response of tissue homogenates prepared from control and 3-methylcholanthrene (3-MC)-treated Sprague-Dawley

CHEMICAL CARCINOGENESIS

rats to antioxidants and sterols was examined. Antioxidants such as butylhydroxyanisole and butylhydroxytoluene inhibited the mixed-function oxidation of benzo(a)pyrene (BP) in several tissues of control and 3-MC-treated rats. The enzyme systems in the liver, kidney, and stomach were much more susceptible to inhibition than those in the lung, adrenals, colon, and small intestine. In all tissues except the stomach, 3-MC treatment led to a decrease in the inhibition of BP 3-hydroxylase activity. It is suggested that antioxidants protect against cancer development by inhibiting the formation of carcinogenic metabolites. Of the various steroids tested, only 17 β -estradiol and estrone were significantly inhibitory in most tissues. Cholesterol increased BP 3-hydroxylase activity in the gastrointestinal tract. (45 refs)

- 79-5075 **Prolactin and 3-Methylcholanthrene Induced Cervical Carcinoma. Effect of Bromocriptine.** (Eng) Forsberg, J. G. (Inst. Anatomy, Univ. Bergen, Arstadvollen 19, N-5000 Bergen, Norway); Breistein, L. S. *Acta Pathol Microbiol Scand [A]* 87(3): 151-156; 1979.

Female mice of the NMRI strain were estrogenized by injection with estradiol for the first five days after birth and ovariectomized at the age of 6-9 wk. One wk later, a cotton thread impregnated with 3-methylcholanthrene was inserted into the uterine cervix. Starting on the day of insertion of the thread, and for an additional 6 days, the females were injected with estradiol (E_2 , 5 μ g), ovine prolactin (P, 5 μ g), or 2-bromo- α -ergokryptine mesylate (bromocriptine, 50 μ g), alone or in different combinations. Controls were injected with vehicles only. The animals were killed 4 or 8 wk after insertion of the thread, and the uterine cervix was serially sectioned. A combined treatment with E_2 and P resulted in an increased incidence of invasive epithelial lesions (epidermoid carcinomas of varying stages of differentiation, and one adenocarcinoma) in the uterine cervix. This incidence was higher than in controls or females injected with either hormone separately. Bromocriptine reduced the incidence of invasions, and this reduction could not be restored to the control level by a simultaneous treatment with E_2 and/or P. Finally, the incidence of invasive lesions in the control group of these estrogenized females was higher than that reported in an earlier study using nonestrogenized females. (11 refs)

- 79-5076 **Gastrinoma Associated with Common Bile Duct Obstruction and the Ectopic Production of ACTH.** (Eng) Kyriakides, G. K. (Dept. Surgery, Univ. Miami Sch. Medicine, P.O. Box 016310, Miami, FL 33101); Silvis, S. E.; Ahmed, M.; Vennes, J. A.; Vogel, S. B. *Am J Surg* 137(6): 800-802; 1979.

A case of adrenocortical hyperfunction due to the ectopic production of ACTH by a gastrin-producing pancreatic

tumor occurred in a 41-yr-old man. Cushing's syndrome preceded the appearance of the overt Zollinger-Ellison syndrome by 2 yr. There is evidence that the pancreatic gastrinoma was the source of the ectopic production of ACTH and, possibly, secretin. (14 refs)

- 79-5077 **Membrane Effects of Tumor Promoters: Stimulation of Sugar Uptake in Mammalian Cell Cultures.** (Eng) Lee, L. S. (Cancer Center/Inst. Cancer Res., Columbia Univ. Coll. Physicians and Surgeons, 701 W. 168th St., New York, NY 10032); Weinstein, I. B. *J Cell Physiol* 99(3): 451-460; 1979.

The effects of the potent tumor-promoting agent, 12-O-tetradecanoylphorbol-13-acetate (TPA), on sugar transport in human, rat, and murine cells were studied. TPA induced a 12-fold stimulation of 2-deoxy-D-glucose (DG) uptake in confluent 3T3 mouse embryo fibroblasts and a 2.5-fold stimulation in HeLa S3 cells. When a series of macrocyclic diterpenes were assayed, their relative potencies in stimulating DG uptake in 3T3 cells correlated with other known biologic effects of these compounds. On a molar basis, TPA was a much more potent stimulator of DG transport than insulin or epidermal growth factor. In HeLa cells, the ED_{50} value of the TPA effect was 0.2 nanomolar. The increase in DG uptake occurred immediately after the addition of TPA, reached a max at 90 min, persisted for at least 3 hr after the removal of TPA from the medium, and was temperature-dependent. The stimulation was not inhibited by cycloheximide or actinomycin D. As in control cells, DG uptake in TPA-treated cells was inhibited by p-hydroxymercurobenzoate, phloridzin, cytochalasin B, and dexamethasone. Although the precise mechanism is not known, evidence is presented that the TPA stimulation of DG uptake is due to enhanced transport of the sugar rather than to effects on intracellular metabolism. The enhanced transport may be secondary to a more generalized change in membrane structure. (43 refs)

- 79-5078 **Diethylstilbestrol and 11 Derivatives. A Mutagenicity Study with *Salmonella typhimurium*.** (Eng) Glatt, H. R. (Institute Pharmacology, Sect. Biochemical Pharmacology, Univ. Mainz, Mainz, W. Germany); Metzler, M.; Oesch, F. *Mutat Res* 67(2): 113-121; 1979.

Diethylstilbestrol (DES) was tested for mutagenicity in *his-Salmonella typhimurium* strains under 10 different metabolic situations (no exogenous metabolizing system; S9 mix from liver homogenate of rats induced with Aroclor 1254, with or without inhibition of epoxide hydratase; liver and/or kidney S9 mix from control or hamsters treated with Aroclor 1254; horse-radish peroxidase + H_2O_2).

Under none of these conditions did DES give any indication of a mutagenic effect. Furthermore, 11 metabolites and other DES derivatives, 2 of them potent inducers of sister-chromatid exchange in cultured fibroblasts, were not mutagenic in any of the tester strains (*S. typhimurium* TA100, TA98, TA1537, TA1535) in the presence or absence of S9 mix from liver homogenate of rats induced with Aroclor 1254. Thus, one of the few known human carcinogens is very resistant to detection by the mammalian enzyme-mediated *S. typhimurium* mutagenicity assay (Ames test). This is especially remarkable since the metabolizing systems used included: (1) some of very high metabolic activity (S9 mix from liver homogenates of rats and hamsters induced with Aroclor 1254); (2) metabolizing systems from organs susceptible to the carcinogenic activity of DES (hamster kidney); and (3) a mixture of (1) and (2) in case both activities are required for the carcinogenic effect in the whole animal. (23 refs)

- 79-5079 Cytogenetic Effects of Diethylstilbestrol-diphosphate (DES-dp) on Mouse Bone Marrow Monitored by the Micronucleus Test. (Eng) Chrisman, C. L. (Dept. Animal Sciences, Purdue Univ., West Lafayette, IN 47907); Baumgartner, A. P. *Mutat Res* 67(2): 157-160; 1979.

Six doses of diethylstilbestrol diphosphate (DES-dp), ranging from 0.01 to 500 mg/kg, were compared with saline and phosphate buffered saline (negative controls) and two doses (10 and 100 mg/kg) of cyclophosphamide (positive control) in the micronucleus test with 115 ICR mice. DES-dp failed to generate a significant increase in micronucleated polychromatic erythrocytes over negative controls. Cyclophosphamide produced a dose-related increase in micronuclei similar to previously published reports. It is concluded that the micronucleus test does not detect the types of chromosomal changes known to be produced by DES-dp and DES. (21 refs)

- 79-5080 DES-stimulated Increase in Leydig Cell LH Receptors in Mouse Strain Susceptible to Estrogen-induced Testicular Tumors (Meeting Abstract). (Eng) Navickis, R. J. (Dept. Reproductive Medicine, Univ. California, San Diego, CA); Hsueh, A. J. *Biol Reprod* 20(Suppl 1): 57A; 1979 (no refs)

- 79-5081 Preparation of the Radioiodinated Histamine Amide of 4-O-(Carboxypropyl)diethylstilbestrol. (Eng) Johnson, H. J. (Dept. Biochemistry, Univ. Arkansas Coll. Medicine, Little Rock, AR 72201); Cer-

nosek, S. F.; Gutierrez-Cernosek, R. M. *J Labelled Compd Radiopharm* 16(3): 501-506; 1979.

The synthesis of a radioiodinated derivative of diethylstilbestrol (DES) by the mixed anhydride coupling reaction is described. With this method, it is possible to avoid introducing iodine directly into the ring structures. Histamine is labeled by the oxidative Chloramine-T method before it is coupled to 4-O-(carboxypropyl)diethylstilbestrol (I). I is prepared by O-alkylation of DES with ethyl 4-bromobutyrate and alkaline hydrolysis of the ethyl ester. Reaction of I with isobutylchloroformate in dioxane in the presence of tri-n-butylamine gives the mixed anhydride, which is then coupled to ¹²⁵I-histamine to give the ¹²⁵I-histamine amide derivative. This derivative demonstrated immunoreactivity when assayed with an antibody to DES (30% bound at a 1/1,000 dilution of the antiserum), thus making possible a potentially useful iodine-based radioimmunoassay for DES. - 79-5082 Nutritional and Endocrinological Influences of Graded Levels of Calcium and Diethylstilbestrol upon Bone Density and Kidney Mineralization in Mature Rats (Meeting Abstract). (Eng) Kirkowski, A. C. (Cook Coll., Rutgers Univ., New Brunswick, NJ 08903); Evans, J. L. *J Nutr* 109(6): 33; 1979 (no refs)

- 79-5083 Oestrogen-induced Renal Carcinoma. (Eng) Nissenkorn, I. (Dept. Urology, Beilinson Medical Centre, Petah Tiqva, Israel); Servadio, C.; Avidor, I. *Br J Urol* 51(1): 6-9; 1979.

Two patients (aged 65 and 70 yr) who had been treated for prostatic carcinoma with low-dose diethylstilbestrol (3 mg/day) for 3.5 and 3 yr, respectively, developed renal carcinomas. The first patient was admitted for disturbances in micturition. Physical examination was unremarkable except for slight tenderness over the left loin and a small, firm, nodular prostate. Excretory urogram revealed a non-functioning left kidney. Left retrograde pyelography demonstrated a filling defect in the renal pelvis and a normal ureter. Histological examination of the resected tumor revealed a renal carcinoma penetrating into the calices and renal pelvis. The tumor mass infiltrated the upper ureter and extended through the renal capsule into the perirenal tissue. The second patient was being treated for a pathological fracture of the left femur. Histological examination of a specimen from the fractured femur revealed metastatic renal carcinoma, and excretory urography demonstrated a space-occupying lesion in the left kidney. Distant metastases were found in the thoracic vertebrae in the first patient and in the liver and left femur in the se-

cond. Patients with prostatic carcinoma receiving prolonged estrogen therapy should undergo iv pyelography at regular intervals. (9 refs)

- 79-5084 A Novel Fluorinated Derivative of Diethylstilbestrol. (Eng) McLachlan, J. A. (Natl. Inst. Environmental Health Sciences, Research Triangle Park, NC 27709); Baucom, K.; Korach, K. S.; Levy, L.; Metzler, M. *Steroids* 33(5): 543-547; 1979.

The synthesis of a diethylstilbestrol (DES) derivative (tetrafluorodiethylstilbestrol, TFDES) with fluorine atoms present in positions ortho to the hydroxyl in each ring is described. TFDES showed extensive oxidation in vitro to the corresponding dienestrol derivative, and at 100 µg/kg, TFDES and DES had comparable in vivo uterotrophic activities. Competitive binding experiments showed that TFDES was 20-25 times less reactive than DES in the mouse uterine estrogen receptor assay. (13 refs)

- 79-5085 Lack of Oestradiol-DNA Binding in Mouse Embryo Cell Cultures or Following Rat-Liver Microsomal Metabolism. (Eng) Duncan, S. J. (Chemical Carcinogenesis Div., Inst. Cancer Res., Pollards Wood Res. Station, Nightingales Lane, Chalfont St. Giles, Buckinghamshire HP8 4SP, England); Brookes, P. *Cancer Lett* 6(6): 351-355; 1979.

The binding of estradiol-17β to the DNA of mouse embryo cells in culture and to DNA added to a microsomal incubation was examined and compared to the binding of benzo(a)pyrene (BP) to DNA. Primary mouse embryo cell cultures were treated with (³H)BP or (³H)estradiol-17β at a concentration of 0.04 µg/ml of medium. In the microsomal incubation, the (³H)estradiol-17β (5 Ci/mmol) or (³H)BP (133 Ci/mol) were added at a concentration of 100 nmol/ml. The level of BP binding was 1.0-1.5 µmol/mol P compared to 0.01 µmol/mol P for estradiol-17β. When the DNA was isolated from the microsomal incubation by a phenol extraction followed by alcohol precipitation, the binding level of estradiol-17β was similar to that of BP. However, when the DNA was isolated using the conventional procedure to obtain DNA from cells, the apparent level of estradiol-17β binding was reduced by >85% while the BP binding level remained unchanged. The results give no evidence that estradiol-17β is metabolized by a cytochrome-P-448 oxidase system to a molecular species which is capable of covalent binding to DNA. It seems, however, that NADPH-requiring microsomal metabolism of estradiol results in association of the hormone with a DNA containing complex. This might be explained if specific estrogen-binding proteins had an affinity for DNA. (12 refs)

- 79-5086 A Case of Hepatocytic Adenoma Following Estrogen-Progestogen Treatment. Review of the Published Literature. (Fre) Grandjean, J. P. (Polyclinique Sainte Marie-Therese, 10 avenue Franklin-Roosevelt, 69500 Bron, France); Vignal, J.; Seffert, P.; Mestrallet, G.; Beurlet, J.; Quiviger, P. *Ann Chir* 33(5): 361-370; 1979.

A large hepatocytic adenoma was found in a 30-yr-old woman who had intermittently used oral contraceptives for 8 yr. She had taken ethynodiol diacetate and ethinyl estradiol for 39 mo, then again for 30 mo after a 17-mo intermission; recently, she had taken norethisterone acetate and ethinyl estradiol. Surgery was successful. A total of 160 cases have been reported in the literature. Stopping the use of the oral contraceptives seems to prevent recurrences after surgery, but it is not known whether this measure is sufficient to produce regression of these benign tumors. (58 refs)

- 79-5087 Relationship Between the Uterotropic Effects of 17β-Estradiol and P-1496 and Their Ability to Bind to Estrogen Receptors. (Ita) Iacobelli, S. (Istituto di Clinica Ostetrica e Ginecologica, Universita Cattolica del Sacro Cuore, Rome, Italy); Zenobi, R.; Ranelletti, F. O.; Bompiani, A. *Riv Ital Ginecol* 58(3): 175-182; 1979.

The uterotrophic effects of 6-(dihydroxyundecyl)-β-resorcylic acid-μ-lactone (P-1496) and 17β-estradiol (ED) were compared with the capacity of these compounds to bind to uterine estrogen receptors. The uterotrophic activity of P-1496 was 20 times lower than that of ED, and the affinity of P-1496 for estrogen receptor sites was about 1/20 that of ED. P-1496 and ED bound to the same estrogen receptors. (5 refs)

- 79-5088 Oestrogen Therapy and Endometrial Carcinoma (2 Letters to Editor). (Eng) Studd, J. W. (Dept. Obstetrics and Gynaecology, King's Coll. Hosp., London SE5, England); Thom, M.; Patterson, M. *Lancet* 1(8128): 1239; 1979.

Prolonged usage of unopposed estrogen therapy may, in susceptible patients, produce endometrial cancer, but there is good evidence that the addition of progestagen prevents this increased rate of cancer and, also, hyperplasia. There is no evidence that low-dose cyclical estrogen with progestagen is in any way associated with an increased risk of endometrial cancer. Therefore, 7-13 days of a progestagen should be added each month so that the benefits of estrogen may be achieved with no increased risk of endometrial lesions. (7 refs)

79-5089 Tumors of the Liver and Contraception (Meeting Abstract). (Fre) Monrozies, X. (No affiliation given). *J Gynecol Obstet Biol Reprod (Paris)* 8(1): 75; 1979 (no refs)

79-5090 Mutagenicity in Urine of Nurses Handling Cytostatic Drugs (Letter to Editor). (Eng) Falck, K. (Dept. Industrial Hygiene and Toxicology, Inst. Occupational Health, SF-00290 Helsinki 29, Finland); Grohn, P.; Sorsa, M.; Vainio, H.; Heinonen, E.; Holsti, L. R. *Lancet* 1(8128): 1250-1251; 1979.

A sensitive screening procedure using *Escherichia coli* strain WP2 uvrA and *Salmonella typhimurium* strains TA98 and TA100 as indicator organisms was used to detect mutagenic activity in the urine of patients on chemotherapy and of nurses administering these drugs. All patients receiving cytostatic drugs exhibited mutagenicity in their urine, as did most of the nurses. The mutagenicity was significantly higher in the patients' urines. (7 refs)

79-5091 The Response of Ataxia Telangiectasia Cells to Bleomycin. (Eng) Lehmann, A. R. (MRC Cell Mutation Unit, Univ. Sussex, Falmer, Brighton BN1 9QG, England); Stevens, S. *Nucleic Acids Res* 6(5): 1953-1960; 1979.

Cultured fibroblasts from patients with ataxia-telangiectasia (AT) were sensitive to the lethal effects of bleomycin (BM). As with ionizing radiation, no defects were observed in the overall rejoining of the single- or double-stranded breaks produced by BM. However, since only apyrimidinic (and, to a lesser extent, apurinic) sites are produced by BM, it is tentatively suggested that AT cells are unable to rejoin a very small fraction of the total strand breaks. (29 refs)

79-5092 Effects of Trialkyltin Compounds on *Escherichia coli* JE 1011 and Its NS Mutants. (Jpn) Tatsuguchi, K. (Dept. Food Science and Technology, Kyusyu Univ., Fukuoka 812, Japan); Setokuchi, T.; Yamada, J.; Watanabe, T. *Nippon Nogeikagaku Kaishi* 53(3): 81-86; 1979.

Antimicrobial actions of trialkyltin compounds on *Escherichia coli* JE 1011 and its NS mutants were investigated. Triethyltin chloride (TET) revealed similar antimicrobial action on JE 1011 and NS mutants, and tripropyltin chloride (TET) showed more activity on NS mutants than on JE 1011. Tributyltin chloride (TBT) was effective only on NS mutants. The partition coefficients of TET, TPT and TBT [1-octanol/0.05 M sodium phosphate (pH 7.0) buffer system at 20 C] were 2.5, 22 and 49, respec-

tively, indicating that the greater the carbon number in the alkyl chain of a compound, the more hydrophobic it will be. Lipopolysaccharides (LPS) and protein were rapidly released from JE 1011 treated with EDTA. Antimicrobial action on JE 1011 was increased in the case of TPT and TBT by EDTA treatment of the cells, especially in TBT, but not in TET. The results and data on the LPS of these strains suggests that the outer membrane of JE 1011 is a permeability barrier for TPT and TBT, which are more hydrophobic than TET. (20 refs)

79-5093 The Triplet State of 8-Methoxypsoralen. (Eng) Sloper, R. W. (Dept. Chemistry, Paisley Coll., Paisley, PA1 2BE, Scotland); Truscott, T. G.; Land, E. J. *Photochem Photobiol* 29(5): 1025-1029; 1979.

The transient absorption spectra produced by laser flash photolysis of an aqueous soln of 8-methoxypsoralen (8-MOP) were studied. The biphotonic production of hydrated electrons and of the radical ions 8-MOP⁺ and 8-MOP⁻ is reported. The hydrated electron reacted with ground state 8-MOP with k approx $3 \times 10^{10} M^{-1}s^{-1}$. To obtain a true triplet-triplet absorption spectrum, contributions from the radical ions were subtracted from the overall transient absorption. In addition, contributions from the solvated electron (e_{aq}) to the transient spectrum were removed by using N₂O, low laser intensity to minimize photoionization, or by measuring the transient optical density after the electron had decayed. These three methods each produced the same triplet-triplet spectrum that differs in the red region from previously reported spectra. (21 refs)

79-5094 Formation and Identification of Tetra- and Pentachlorobenzo-p-dioxins from Photolysis of Two Isomeric Hexachlorodibenzo-p-dioxins. (Eng) Buser, H. R. (Swiss Federal Res. Station, CH-8820 Wädenswil, Switzerland). *Chemosphere* 8(4): 251-257; 1979.

The formation of tetra- and pentachlorinated dibenzo-p-dioxins (CDD's) from the UV photolysis of 1,2,3,6,7,8- and 1,2,3,7,8,9-hexa-CDD was studied. Both of these compounds also formed smaller amounts of lower chlorinated dioxins. Each of the hexa-CDDs formed three penta-CDD isomers, all with 3:2 substitutions. They also formed one major, two medium-sized, and up to five minor tetra-CDD isomers, most of them with 2:2 chlorine substitutions. In both cases there was a preferential dechlorination of the hexa-CDD's occurring at the lateral positions flanked on both sides by adjacent chlorines. Two of the minor tetra-CDD's from each hexa-CDD possessed 3:1 chlorine substitutions. The main reaction pathways of the photolytic dechlorination of the two hexa-CDD's are illustrated. (8 refs)

79-5095 Stimulation of Iron Absorption by Polychlorinated Aromatic Hydrocarbons. (Eng) Manis, J. (Div. Gastroenterology, Dept. Medicine, State Univ. New York, Downstate Medical Center, Brooklyn, NY 11203); Kim, G. *Am J Physiol* 236(6): E763-E768; 1979.

The effects of 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) and 1,1,1-trichloro-2,2-bis(p-chlorophenyl)ethane (DDT) on iron absorption were investigated in male Sprague-Dawley rats. Rats were given 0.05 ml dioxane with or without TCDD (33 µg/kg) po or ip, and Fe transport was studied in the duodenal loops in vivo after 1-2 days. Transfer of Fe to the blood or carcass was increased 67% and 41%, respectively, by po and ip treatment. In contrast, the first step of Fe absorption, mucosal uptake, increased only 10% after the po dose and not significantly after the ip dose. Thus, the major effect is on Fe transfer from the mucosa into the bloodstream rather than on the Fe uptake from the lumen of the gut. The results were confirmed in studies with everted gut sacs. The effect was max at 1-2 days with a dose of 22-42 µg/kg. Calcium transport was inhibited by TCDD, but galactose and proline transport were unaffected. DDT (200-800 mg/kg in 0.2 ml dioxane, po) also stimulated Fe transport. The stimulation of Fe transport by TCDD was accompanied by an increase in aryl hydrocarbon hydroxylase activity in the intestine and liver. The results suggest that polychlorinated aromatic hydrocarbons may affect the intestinal absorption of essential mineral nutrients. They

also provide further evidence for the two-step mechanism of Fe absorption. (31 refs)

PHYSICAL CARCINOGENESIS

- 79-5096 Detection of Chromosome Aberrations in B Lymphocytes of Atomic Bomb Survivors. (Jpn) Kamada, N. (Dept. Internal Medicine, Res. Inst. Nuclear Medicine and Biology, Hiroshima Univ., Hiroshima, Japan); Oguma, N.; Tanaka, R.; Pant, G. S.; Kuramoto, A.; Katsuki, T.; Hinuma, Y.; Morita, M.; Abe, T. *Jpn J Clin Hematol* 20(4): 346-354; 1979.

The presence of chromosome aberrations in the B lymphocytes of four atomic bomb survivors was detected by a new method in which the Epstein-Barr virus (EBV) sensitivity of B lymphocytes was used to isolate and culture cells in mitosis. All four subjects (2 women and 2 men aged 15-37 yr at the time of the bomb) had been 550-750 m from the epicenter of the explosion and had received an estimated 200-638 rads. EBV-sensitive B lymphocytes isolated from the peripheral blood lymphocytes of the subjects were initially cultured on soft agar and then transferred to a liquid culture for further growth. When stained and examined under a microscope, the B lymphocytes of 2/4 survivors showed chromosome aberrations. Of the cells that were able to be analyzed, 8/16 cells from the survivor exposed to 638 rads and 3/24 cells from the survivor exposed to 400 rads contained aberrant chromosomes. Chromosome aberrations were also observed in the T lymphocytes and bone marrow cells of all four subjects. The development of acute B-lymphocytic leukemia, B-cell lymphoma, or multiple myeloma may be elucidated by this technique of isolating and culturing B lymphocytes. (22 refs)

- 79-5097 Chromosome Aberrations in B Lymphocytes of Atomic Bomb Survivors. (Eng) Kamada, N. (Res. Inst. Nuclear Medicine and Biology, Hiroshima Univ., 1-2-3 Kasumi-cho, Hiroshima 734, Japan); Kuramoto, A.; Katsuki, T.; Hinuma, Y. *Blood* 53(6): 1140-1147; 1979.

A method for detecting chromosome aberrations in B lymphocytes is described that involves stimulation of B lymphocytes with Epstein-Barr virus (EBV) instead of separation of B lymphocytes by rosette formation. The EBV-stimulated lymphocytes were isolated as single colonies in soft agar and transferred to liquid culture for further growth. The EBV-stimulated B lymphocytes of two heavily exposed atomic bomb survivors showed 50% and 12.5% chromosome abnormalities 30 yr after exposure. The former patient seemed to have a karyotypically abnormal clone of B lymphocytes in vivo. The detection method used and the evidence of chromosome aberrations in B lymphocytes a long time after radiation exposure will be useful

and important in elucidating the processes involved in the development of acute lymphocytic leukemia, B-cell lymphoma, and multiple myeloma among high-risk groups having a history of accidental or therapeutic exposure to radiation or radiomimetic drugs. (14 refs)

- 79-5098 Deposition and Accumulation of Plutonium Isotopes in Antarctica. (Eng) Cutter, G. A. (Center Coastal Marine Studies, Univ. California, Santa Cruz, CA 95064); Bruland, K. W.; Risebrough, R. W. *Nature* 279(5714): 628-629; 1979.

Data on the deposition of plutonium isotopes from the atmosphere at Dome C on the high Antarctic plateau are presented. Profiles of Pu activities suggest that almost all the Pu isotopes injected into the atmosphere have now been removed. The activities of both $^{239} + ^{240}\text{Pu}$ and ^{238}Pu deposited during 1976 at Dome C were only 1.4% of the activities deposited during their respective periods of maximum fallout. (17 refs)

- 79-5099 Tumor-Susceptibility Generated in Mice Treated with Subcarcinogenic Doses of 8-Methoxypsoralen and Long-Wave Ultraviolet Light. (Eng) Roberts, L. K. (Radiobiology Lab., Dept. Anatomy, Univ. Utah Medical Center, Salt Lake, UT); Schmitt, M.; Daynes, R. A. *J Invest Dermatol* 72(6): 306-309; 1979.

The effects of acute treatments with short-wave UV light (UVB) or with 8-methoxypsoralen (8-MOP) followed by long-wave UV light (PUVA) on the growth of an sc inoculated, UV-induced regressor tumor (RD 87) were studied in female C3Hf/HeN mice. Mice treated with PUVA were as susceptible to tumor challenge as mice treated with UVB. Treatment with 8-MOP or UVA alone resulted in tumor rejection. The rate of tumor growth was similar in mice treated with UVB and PUVA and greater in animals treated with UVB or PUVA than in those treated with UVA ($p \leq 0.01$). Treatment of PUVA-treated mice with anti-immune-associated antigen [anti-Ia(k)] serum abrogated their ability to support tumor growth, indicating that the tumor-susceptible state in PUVA-treated mice is mediated or influenced by an Ia⁺ suppressor cell. - 79-5100 Enhancement of Aryl Hydrocarbon Hydroxylase Activity in Cultured Rodent Cells by

PHYSICAL CARCINOGENESIS

X-Irradiation. (Eng) Venkatesan, N. (Div. Hematology-Oncology, Childrens Hosp. Los Angeles, Los Angeles, CA 90027); Alfred, L. J.; Torralba, G.; Benedict, W. F. *Life Sci* 24(9): 797-802; 1979.

The effect of x-irradiation (5,000 rads) on the aryl hydrocarbon hydroxylase (AHH) activity of mouse C3H/10T1/2 CL8 cells, Syrian hamster embryo (SHE) cells, and hamster fibrosarcoma A(T₁) Cl-3 cells was studied. Irradiation alone increased the AHH activity of the fibrosarcoma cells by 225% and 217%, respectively, expressed on the basis of DNA and protein ($p < 0.001$). Irradiation prior to induction by benz(a)anthracene (BA, 5 or 15 $\mu\text{g/ml}$) increased the activity 157% and 154% on the basis of DNA and protein, respectively, over the additive effects of both agents ($p < 0.001$). Irradiation alone increased the AHH activity of SHE cells by 55% expressed per mg of DNA ($0.005 > p > 0.001$), and irradiation plus BA increased the activity 28% over the additive effects of both agents. Irradiation alone increased the AHH activity of the mouse cells by 86% ($p < 0.001$) and irradiation plus BA increased the activity 59% over the additive effects of both agents ($p < 0.001$). A synergistic effect was also seen with mouse cells treated with 300 rads. (22 refs)

79-5101 Sister Chromatid Exchanges in Human Lymphocytes Exposed to Ionizing Radiation during G₀. (Eng) Littlefield, L. G. (Medical and Health Sciences Div., Oak Ridge Associated Universities, Radiation Emergency Assistance Center and Training Site, Oak Ridge, TN 37830); Colyer, S. P.; Joiner, E. E.; DuFrain, R. J. *Radiat Res* 78(3): 514-521; 1979.

Several authors have reported small, but statistically significant, increases in sister chromatid exchanges (SCE's) in mammalian cells exposed to low-linear energy transfer (LET) radiation during culture in the presence of [³H]-thymidine or bromodeoxyuridine (BUdR). To determine whether ionizing radiation also induces lesions in the unsubstituted DNA of G₀ lymphocytes that lead to SCE's in second division metaphases, human lymphocytes were exposed to 150 or 300 R ⁶⁰Co- γ radiation prior to culture in the presence of phytohemagglutinin and BUdR. Increased frequencies of SCE's were not observed in the irradiated cultures, either in second division metaphases having ring and dicentric chromosomes or those that did not have detectable chromosome aberrations. These findings suggest that SCE frequencies would not be increased in cultured lymphocytes from persons with in vivo exposures to radiation, and they raise questions regarding the efficacy of ionizing radiation in inducing long-lived lesions in native DNA that can subsequently be expressed as SCE's. (30 refs)

79-5102 Fibrosarcoma after Proton-Beam Pituitary Ablation. (Eng) Coppeto, J. R. (1906 N. Main

St., Waterbury, CT 06704); Roberts, M. *Arch Neurol* 36(6): 380-381; 1979.

The occurrence of a brain fibrosarcoma in a 46-yr-old man who had undergone proton-beam ablation of the pituitary 7 yr previously is reported. The first symptoms were headache, loss of libido, polyuria, polydipsia, and constant, painless vertical diplopia. Examination revealed blepharoptosis, in the left eye, mild weakness of the left superior rectus muscle, left-sided anosmia, and acromegalic facies. Biopsy of the floor of the frontal horns 5 mo later suggested glioblastoma multiforme. Soon afterward, horizontal diplopia developed as did bilateral, complete internal and external ophthalmoplegia. The patient died from a pulmonary embolism. There was no evidence of neoplasia outside the central nervous system, but the cavernous sinus and sella were diffusely infiltrated with fibrous tumor which extended forward into the frontal lobes. The tumor was a fibroblastic neoplasm with notable anaplasia and cellular pleomorphism suggestive of malignant fibrous histiocytoma. (10 refs)

79-5103 Acute Myeloid Leukemia During Hodgkin's Disease. (Pol) Dziewulska-Bokiniec, A. (Klinika Radioterapii, Instytut Radiologii i Radioterapii Akademii Medycznej, ul. Debinki 7, 80-211 Gdansk, Poland); Jassem, J. *Acta Haematol Pol* 10(2): 137-140; 1979.

Acute myeloid leukemia developed in a 35-yr-old woman 5 yr after a diagnosis of Hodgkin's disease (HD). She had been treated for the HD with telecobalt radiation (tumor dose 4,500 rads in 5 wk), vinblastine (VLB, 10 mg/wk, 6 iv injections), procarbazine (150 mg/day po for 5 mo), and with the MOPP protocol (VLB, nitrogen mustard, procarbazine, and prednisone; 6 cycles). The leukemogenic effect of intensive radiotherapy and chemotherapy is discussed. (23 refs)

79-5104 Multiple Keratoacanthomas and Squamous Cell Carcinomas Occurring at Psoriatic Treatment Sites. (Eng) Maddin, W. S. (Faculty Medicine, Univ. British Columbia, Vancouver, British Columbia, Canada); Wood, W. S. *J Cutan Pathol* 6(2): 96-100; 1979.

Four cases of psoriasis in which a spectrum of new growths occurred in conjunction with the psoriasis are reported. A 52-yr-old woman developed over 50 new skin lesions beginning 13 yr after the onset of psoriasis. The lesions, which occurred in sites most heavily involved by psoriasis, included benign keratoses, actinic keratosis, in situ squamous cell carcinomas, well-differentiated invasive squamous cell carcinomas, and keratoacanthomas. A 70-yr-old man developed five lesions (including two infiltrating squamous cell carcinomas, an actinic keratosis with in situ squamous

cell carcinoma, and a keratoacanthoma) in areas most heavily involved by psoriasis; the first new lesion appeared 14 yr after psoriasis. A 53-yr-old woman developed multiple keratoacanthomas and squamous cell carcinomas in the areas most heavily involved by psoriasis beginning 36 yr after the appearance of psoriasis. A 53-yr-old man developed a single infiltrating squamous cell carcinoma in a psoriatic plaque 16 yr after the onset of psoriasis. Two of the four patients had deficient immunological responses. It is concluded that multiple treatment measures (topical mediations, systemic immunosuppressive agents, UV light, and grenz rays) may be the main etiologic factor in the production of cutaneous neoplasms in psoriatic patients. (24 refs)

- 79-5105 Basal Cell Epithelioma in a BCG Vaccination Scar (Letter to Editor). (Eng) Nielsen, T. (Odense, Denmark). *Arch Dermatol* 115(6): 678; 1979.

The case report of a 52-yr-old woman in whom basal cell epithelioma and cicatricial stroma occurred in a BCG vaccination scar is presented. The patient had been vaccinated 10 yr before the development of the lesion, in 1968, and she had undergone surgery for a superficial melanoma of the lower part of her left leg during the same year. (5 refs)

- 79-5106 The Disposition of Americium-241 Oxide Following Inhalation by Beagles. (Eng) Craig, D. K. (Biology Dept., Pacific Northwest Lab., Richland, WA 99352); Park, J. F.; Powers, G. J.; Catt, D. L. *Radiat Res* 78(3): 455-473; 1979.

The disposition of americium-241 in beagles was followed for up to 810 days after a single inhalation exposure to $^{241}\text{AmO}_2$ aerosols with an activity median aerodynamic diameter (AMAD) of $1.3\ \mu\text{m}$ and a geometric standard deviation (GSD) of 1.8 for medium (approx 40 nanocurie (nCi)/liter) and high (approx 340 nCi/liter) concentrations. At low concentrations ($<1\ \text{nCi/liter}$), the aerosols were similar (AMAD approx $0.6\ \mu\text{m}$) and the distribution broader (GSD approx 2.6). Excreta were analyzed for up to 30 days postexposure and, when appropriate, during the last week before sacrifice. Tissue analyses for ^{241}Am were conducted on groups of three dogs sacrificed 10, 30, 90, 270, and 810 days postexposure. Forty percent of the final body burden of ^{241}Am was located in tissues other than the lung parenchyma by 10 days postexposure and only 6% remained in the lung by 810 days postexposure. Translocation was primarily to the liver and skeleton, with roughly equal fractions of the final body burden in each at all sacrifice times. There was very little retention in the thoracic lymph nodes ($<1\%$), and ^{241}Am activity in the gonads was negligible ($<0.05\%$) for these dogs. Both the rate of translocation and the organ distribution as a function of time were different from those found in dogs that

inhaled $^{238}\text{PuO}_2$ or $^{239}\text{PuO}_2$. Therefore, data derived from $^{239}\text{PuO}_2$ experiments should not be used to predict the behavior of other transuranic isotopes and elements. (28 refs)

- 79-5107 Tracheal Carcinoma after Tracheostomy. (Eng) Weismann, R. A. (Dept. Surgery, UCLA Sch. Medicine, Los Angeles, CA 90024); Konrad, H. R. *Arch Otolaryngol* 105(6): 364-366; 1979.

The development of tracheal carcinoma in the stoma of a 63-yr-old woman who had worn a tracheostomy tube for 27 yr is reported. The patient began to bleed from the stoma, and a biopsy revealed the presence of invasive, moderate to poorly differentiated, squamous cell carcinoma in the tracheal tissue and stomal skin. One year later, chest x-rays revealed paratracheal and superior mediastinal masses that suggested either direct tumor extension or nodal involvement. The patient remained apparently tumor free after a course of radiation therapy. Trauma appears to be a factor in the development of certain malignant tumors of the trachea. The stoma should be examined regularly in any patient who requires prolonged tracheostomy. (11 refs)

- 79-5108 Endobronchial Polyposis Secondary to Thermal Inhalational Injury. (Eng) Adams, C. (Section Pulmonary Medicine and Plastic Surgery, Foster G. McGaw Hosp., Loyola Univ. Chicago, Maywood, IL 60153); Moisan, T.; Chandrasekhar, A. J.; Warpeha, R. *Chest* 75(5): 643-645; 1979.

The case report of a 28-yr-old man who developed endobronchial polyposis as a delayed complication of thermal respiratory injury incurred during a house fire is presented. Symptoms of chronic cough and hemoptysis required bronchoscopic examination 1 mo after admission. Two months after the initial injury, numerous endobronchial polyps were found in the trachea and throughout the bronchial tree. The symptoms subsequently improved over a 6-mo period while the patient was receiving steroid therapy. As far as is known, this delayed complication of inhalation burn injury has not been reported previously. (9 refs)

- 79-5109 Tumor Formation of Rat Ascites Hepatoma Cells in the Traumatized Brain. (Eng) Kawaguchi, T. (Second Dept. Pathology, Fukushima Medical Coll., 5-75 Sugitsuma-cho, Fukushima 960, Japan); Kitamura, H.; Nakamura, K. *Gann* 70(3): 337-342; 1979.

Factors influencing the enhancing effect of physical brain trauma on the formation of brain metastases were examined in female Donryu rats with induced coagulation necrosis

of the cerebral cortex. The rats were then inoculated iv with one of the six strains of rat ascites hepatoma tested. Three of the tumors (AH7974F, AH66F, and AH13) were in the single-cell state and three (AH272, AH7974, and AH601) contained cellular aggregates. None of the tumors produced brain metastases in rats without brain trauma. However, after traumatization of the brain tissue, tumor metastases formed in the lesion, mainly with the single-cell-type tumors. Of the aggregated tumors, only AH272 produced brain metastases. The brain tissue was most susceptible to the tumor cells 10 min or 7 days after trauma induction. On the other hand, after injection of AH13 or AH7974 cells into the carotid artery of traumatized animals, brain metastases were found with both types of tumor. (20 refs)

- 79-5110 Double Tumours of the Liver Following Intravenous Thorotrast Injection. Patho-anatomical Report on Two Cases. (Eng) Wegener, K. (Pathological Inst., Municipal Hosp. Ludwigshafen/Rh., Bremsersstrasse 79, D-6700 Ludwigshafen/Rh., W. Germany); Leipolz-Angermüller, S. *Virchows Arch [Pathol Anat]* 382(1): 63-71; 1979.

A fully developed form of double tumor of the liver derived from the components of the two germ layers following Thorotrast injection and a possible preliminary stage in this process are reported. A 63-yr-old man who had been given Thorotrast 35 yr earlier was found at autopsy to have infiltrating cholangiocellular carcinoma (CCC) of the liver with atypical proliferations of sinusoidal lining cells and metastases in both lungs and the left adrenal. The sinusoidal changes in this case resembled diffuse hemangioendotheliomatosis. A 47-yr-old woman who had been given Thorotrast 34 yr earlier was found at autopsy to have infiltrating CCC of the liver and a hemangioendothelial sarcoma with reticular spreading of tumor cells. The question of whether hemangioendothelial sarcomas are derived from endothelial cells or Kupffer cells is discussed. The number of reported cases of Thorotrast patients with two liver tumors might be low either because postmortem examinations were not performed or because the patients died before the second tumor became established. (33 refs)

- 79-5111 Gastric Carcinoma after Partial Gastrectomy. (Eng) De Boer, J. (Dept. Medicine, Div. Gastroenterology, Univ. Amsterdam, Wilhelmina Gasthuis, Amsterdam, Netherlands); Huibregtse, K.; Tytgat, G. N. *Tijdschr Gastroenterol* 21(3): 157-166; 1978.

The case records, x-rays, and pathological specimens of 100 randomly selected patients (14 women, 86 men) who developed gastric stump carcinoma (GSC) after partial gastrectomy (Ga-x) were analyzed. Eighty-nine patients had a Billroth II resection, 11 a Billroth I. Indications for

Ga-x were gastric ulcer (24), duodenal ulcer (39), and various benign conditions (37). The mean age at Ga-x was 40, and the mean age at diagnosis of the malignancy was 65. The mean interval from Ga-x to diagnosis of GSC was 25.1 yr. The interval was 22.7 and 24 yr for patients who underwent Ga-x for gastric duodenal ulcers, respectively. The younger the patient at initial Ga-x, the longer the interval until diagnosis of GSC. The clinical symptoms for GSC were anorexia, wt loss (73 patients); nausea, vomiting (36); hematemesis, melena (18); dysphagia (17); pain (7); and no symptoms (2). The mean duration of symptoms was 4.8 mo. There was no preference for blood group A. False-negative results were obtained in 16.7% of the patients examined by x-rays, 6.2% of the patients examined by gastroscopy and biopsy. The GSC was located in the anastomotic region in 60%, in the corpus in 18%, and in the cardia in 21%. Undifferentiated adenocarcinoma (AC) was found in 60.3%, well-differentiated AC in 6.8%, and linitis plastica-type AC in 20.5%. The degree of histological differentiation appeared to be inversely related to survival. Damage of the mucosal barrier by duodenogastric reflux, epithelial irritation at the gastro-intestinal junction, chronic atrophic stump gastritis with anacidity, and nitrosamines are implicated in the etiology of GSC. (11 refs)

- 79-5112 Ureterosigmoidostomy and Carcinoma of the Colon. (Eng) Leadbetter, G. W. (Dept. Urology, Medical Center Hosp. Vermont, Burlington, VT); Zickerman, P.; Pierce, E. *J Urol* 121(6): 732-735; 1979.

Two cases of colon carcinoma associated with previous ureterosigmoidostomy (USS) are reported. A 52-yr-old man underwent USS at age 2 yr and a left nephrectomy at 5 yr. A single colon polyp with a moderately well-differentiated adenocarcinoma infiltrating the stalk and superficial portions of the polyp was found at the site of active urine flow. The arrangement of the adenocarcinoma was reminiscent of colitis cystica profunda. A 31-yr-old man who had undergone USS at age 12 yr and a left nephrectomy 3 yr later had a benign lesion at the site of a functional ureteral implant and a moderately differentiated colloid carcinoma at the site of a nonfunctional ureteral implant. Previously reported tumors at the site of USS included 4 cases of benign colonic polyps, 4 transitional cell carcinomas and 29 adenocarcinomas. It has been estimated that USS patients have about a 5% risk of developing carcinoma of the colon at the implant site within 6-50 yr. The colons of individuals <40-yr-old are less susceptible than those of patients >40-yr-old to tumor development. Urine irritation is suggested as the cause of the carcinomas. (34 refs)

- 79-5113 Colonic Adenocarcinomas in Patients with Ureterosigmoidostomies. (Eng) Labow, S. B.

(29 Barstow Road, Great Neck, NY 11021); Hoexter, B.; Walrath, D. C. *Dis Colon Rectum* 22(3): 157-158; 1979.

Two cases of adenocarcinoma of the sigmoid colon developing at the site of a ureterosigmoidostomy (USS) are reported. A 71-yr-old woman presented with adenocarcinoma 41 yr after USS and a 72-yr-old man presented with adenocarcinoma 17 yr after USS. These cases represent the 31st and 32nd reported cases of colonic adenocarcinoma following USS. The av interval between USS and tumor diagnosis was 22 yr, but the av interval was only 9.8 yr in patients who underwent USS because of bladder carcinoma. The etiology of this complication is unknown. It is strongly recommended that careful follow-up of such patients begin several years after establishment of the USS. (16 refs)

79-5114 Carcinoma of Colon after Ureterocolic Anastomosis. Implantation on Calyceal Mucosa. (Eng) Shapiro, A. (Dept. Urology, General Surgery and Pathology, Hadassah Univ. Hosp., Jerusalem, Israel); Berlatzky, Y.; Pfeffermann, R.; Lijovetzky, G.; Caine, M. *Urology* 13(6): 617-620; 1979.

Mucoid adenocarcinoma of the colon developed in two patients (a 37-yr-old woman and a 36-yr-old man) 19 and 34

yr, respectively, after ureterocolic anastomosis for benign conditions. In one patient, a deposit of the colonic neoplasm was found on the mucosa of an upper calyx in the obstructed kidney. This indicates that tumor seeding can occur in the upper urinary tract. Patients who have undergone ureterocolic anastomosis have a greatly increased risk of developing large bowel neoplasms. When suspected, radiologic examination of the colon using a water-soluble contrast material plus rectosigmoidoscopy or colonoscopy are essential. Because of the serious nature of this complication, the recent tendency to use the large bowel in urinary diversions may be hazardous, especially in young patients with a benign disease. (10 refs)

VIRAL CARCINOGENESIS

79-5115 In Vitro Synthesis of Infectious DNA Copies of the Rous Sarcoma Virus Genome. (Eng)

Mariage, R. (Departement de Biologie Cellulaire et Moleculaire, Institut de Cancerologie et d'Immunogenetique, Equipe de Recherche No. 148 du CNRS, 14 avenue Paul-Vaillant-Couturier, F-94800 Villejuif, France); Hill, M. *Intervirology* 11(5): 307-313; 1979.

Attempts were made to synthesize full-length continuous DNA transcripts of viral RNA in vitro. Detergent-disrupted virions of the Prague strain of Rous sarcoma virus (subgroup B) synthesized, in an endogenous reaction, an uninformative DNA that sedimented in neutral sucrose gradients from 18.5S to >28S. The specific infectivity of this DNA, as measured by endpoint dilution transfection assays, was rather low, 34 infectious units/ μ g. Many uninformative molecules of subgenomic length were synthesized, perhaps in part from the defective virions contained in the virus stock. The endogenous reaction yielded up to 8.5×10^{-7} infectious units per biologically active input virion; ie, nearly 0.1-1 infectious molecules. The in vitro-synthesized RSV DNA gave rise to both transforming-nondefective and transforming-defective viruses in the transfection assays. An interference assay, in which the DNA was synthesized in Schmidt-Ruppin RSV (subgroup D) virions, showed that the subgroup specificity of the virus produced by the in vitro-synthesized DNA was the same as that of the parent virus. (23 refs)

79-5116 Biosynthesis of an Unglycosylated Envelope Glycoprotein of Rous Sarcoma Virus in the Presence of Tunicamycin. (Eng) Diggelmann, H. (Swiss Inst. Experimental Cancer Res., 1066 Epalinges, Switzerland). *J Virol* 30(3): 799-804; 1979.

Tunicamycin (TM), an inhibitor of the synthesis of the core sequence for N-glycosidically linked oligosaccharides, was used in an attempt to detect an unglycosylated envelope glycoprotein of Rous sarcoma virus in infected chick embryo fibroblasts. The infected cells were treated with TM (0.1 μ g/ml) to prevent glycosylation of the precursor (pr92gp) to the two viral envelope glycoproteins gp85 and gp35. Pretreatment of the cells with TM for 4 hr resulted in a 90% reduction of [3 H]mannose incorporation into total cellular glycoproteins, intracellular viral glycoproteins, and released virus particles. Protein synthesis and virus particle formation were not significantly affected by the treatment. A new polypeptide made in the presence of TM was identified by immunoprecipitation of pulse-labeled cell lysates with monospecific anti-gp85 and anti-gp35 sera. This

polypeptide, migrating on sodium dodecyl sulfate-polyacrylamide gels as a molecule of 62,000 daltons (pr62), contained no [3 H]mannose, was labeled with [35 S]methionine and [3 H]arginine, could not be chased into the higher-mol-wt glycosylated form, and contained the same [3 H]arginine tryptic peptides as pr92gp. The unglycosylated pr62 was still detectable 2 hr after the cells were pulse-labeled. The lack of glycosylation of pr62 did not seem to reduce its stability. No clear evidence for the incorporation of this molecule or its cleavage products into viral particles could be obtained. To code for an envelope polypeptide of 62,000 daltons, only about 1,500 nucleotides, or 15% of the total coding capacity of the virus, are needed. (19 refs)

79-5117 Genetic Recombination in Rous Sarcoma Virus: The Genesis of Recombinants and Lack of Evidence for Linkage between *pol*, *env*, and *src* Genes in Three Factor Crosses. (Eng) Wyke, J. A. (Imperial Cancer Research Fund Labs., Lincoln's Inn Fields, London WC2A 3 PX, England); Beamand, J. A. *J Gen Virol* 43(2): 349-364; 1979.

The appearance of virus recombinants at early times in mixed infections was studied to identify details of recombination that might otherwise be obscured to the high frequency of recombination. Two Prague strain Rous sarcoma viruses (RSV) distinguishable by host-range differences in the *env* gene and temperature-sensitive (ts) markers in the *pol* and *src* genes were used: ts LA 29 PR-A, which has a ts defect in *src*, and ts LA 355 PR-C, which has a ts defect in *pol*. The former plates on C/C phenotype chick cells but not on C/A phenotype cells; the latter plates on C/A but not C/C cells. In the first type of cross performed, virus was harvested from dually infected cultures after one cycle of replication to see if the progeny produced before reinfection might indicate the stage of infection at which recombination can occur. More than half the virus yield was of parental phenotypes; unequivocal recombinants were rare (8%) and heterozygotes were relatively frequent (24%-32%). Thus, a significant proportion of recombinant genomes appear to arise by segregation of heterozygous virus particles. The members of reciprocal recombinant pairs were not maintained at the same level in the progeny segregating from a heterozygote; during this segregation, one of the markers for a particular gene in the heterozygote apparently becomes more predominant than the other marker. In the second type of cross, both original parental viruses and recombinant viruses from earlier mixed infections were used in longer-than-one-cycle experiments. The levels of reciprocal recombinants were

more equivalent in the mass progeny population than in the previous experiment's progeny population, indicating that there is no restriction on the formation of certain recombinants in these crosses. Linkage between the *pol*, *env*, and *src* genes was very slight, and the progeny arising from double-crossover events were as common as those arising from single-crossover events. Moreover, crosses between all three genes occur at equivalent levels. These results indicate that (1) the three genes are completely unlinked (recombination frequency over the whole genome length is very high and the low level of total recombinants reflects very incomplete mixing of parental genomes) or (2) the genetic map is circular, and the markers are spaced approximately equidistantly along the genome. It is possible that more than one recombination mechanism exists in avian retroviruses. (36 refs)

- 79-5118 Endogenous Virus Expression in Chicken Lines Maintained at the Regional Poultry Research Laboratory. (Eng) Crittenden, L. B. (Regional Poultry Res. Lab., Agricultural Res., U.S. Dept. Agriculture, Science and Education Admin., 3606 E. Mount Hope Road, E. Lansing, MI 48823); Smith, E. J.; Gulvas, F. A.; Robinson, H. L. *Virology* 95(2): 434-444; 1979.

Chicken lines maintained at the Regional Poultry Research Laboratory (RPRL) and free of exogenous lymphoid leukosis virus (LLV) infection were assayed for the expression of endogenous LLV. Embryos were assayed for the expression of infectious subgroup E LLV's, particulate RNA-directed DNA polymerase, antigens that could serve as envelope antigens for the envelope-defective Bryan Rous sarcoma virus (chick helper factor, chf), and the group-specific antigens of the leukosis-sarcoma virus group (gs). RPRL inbred lines 6₁, 6₂, 7₂, 100, and 15B were similar in endogenous virus expression to the previously characterized Beltsville Agricultural Research Center inbred lines 6, 7, 100, and 15. The expression of endogenous LLV was characterized for the first time in three sublines of RPRL line 15 chickens. Line 15₁ was gs⁺ chf⁺; line 15₁₄, gs⁻ chf⁺; and line 15₁₅, gs⁻ chf⁺. Some 15₁ and 15₁₅ embryos produced infectious subgroup E virus, but all 15₁₄ embryos produced infectious subgroup E virus. Two RPRL noninbred lines were also characterized. Line P was segregated for subgroup E virus production and the gs⁺ chf⁺ phenotype. Line N segregated for subgroup E virus production and the gs⁺ chf⁺ and gs⁻ chf⁺ phenotypes. (29 refs)

- 79-5120 Cellular Transformation by Reticuloendotheliosis Virus. (Eng) Franklin, R. B. (Univ. Texas, Austin, TX). *Diss Abstr Int [B]* 39(11): 5238; 1979 (no refs)

- 79-5121 Genetic Control of Resistance to Marek's Disease. (Eng) Longenecker, B. M. (Dept. Immunology, Univ. Alberta, Edmonton, Alberta, Canada); Gallatin, W. M. *IARC Sci Publ* 24(II): 845-850; 1978.

Various Marek's disease (MD)-resistant and MD-susceptible lines of chickens were challenged with an MD tumor cell line (RPL-1) that is capable of growth both in vivo and in vitro. Birds that possessed the B²¹ allele associated with MD resistance were also resistant to the growth of the RPL-1 tumor following the injection of 10⁴ cells. Chickens that possessed B alleles associated with susceptibility to MD were also very susceptible to the growth of the RPL-1 tumor. The growth of RPL-1 cells can therefore be used as a marker of B²¹-associated resistance to MD. Chickens that differ in susceptibility to MD, due to allelic differences at a non-B genetic locus (or loci), did not differ with respect to their capacity to reject RPL-1 cells. This might indicate that different mechanisms are operative in B-associated vs non-B-associated resistance to MD. In addition, females were more susceptible than males to RPL-1 challenge, and the RPL-1 tumor demonstrated a predilection for growth in the ovary. (15 refs)

- 79-5122 Cytotoxicity of Lymphocytes from Chickens with Marek's Disease (MD) to MD Tumour Cell Lines. (Eng) Dambrine, G. (Institut National de la Recherche Agronomique, Station de Pathologie aviaire, Tours-Nouzilly, France); Coudert, F.; Cauchy, L. *IARC Sci Publ* 24(II): 857-862; 1978.

The effect of Marek's disease virus (MDV) infection and oncogenesis on the cytotoxicity of lymphoid spleen cells for MD tumor cell lines (HPRS-1, HPRS-2, and MSB-1) was studied using day-old white Leghorn chickens. Generally, specific cytotoxicity increased with the ratio of lymphoid to target cells and could reach approx 30% for the high ratios. However, at the ratio of 300:1 the specific lysis did not increase as expected. The three lymphoblastoid cell lines were equally destroyed by lymphocytes from chickens with MD. Injection of glutaraldehyde-treated MSB-1 cells in complete Freund's adjuvant into MDV-infected birds did not enhance the in vitro cytotoxicity of spleen lymphoid cells or impair in vivo tumor development. The specific cytotoxic activity exhibited by lymphocytes from MD-infected chickens against MD lymphoblastoid cell lines appears to be directed against the MD tumor-associated surface antigen. VIRAL CARCINOGENESIS

79-5123 Density-Gradient Separation of Spleen-Cell Subpopulations from Marek's Disease Virus-infected Chickens. (Eng) Theis, G. A. (Dept. Microbiology, New York Medical Coll., Valhalla, NY). *IARC Sci Publ* 24(11): 851-856; 1978.

Density-gradient separated spleen-cell subpopulations from FP chickens infected with Marek's disease virus (MDV) were studied to test the hypothesis that the primary cause of depressed mitogen responses in MD is a depletion of mitogen-responsive T lymphocytes. After gradient separation of normal chicken spleen cell suspensions (NS), cells of greater density in fractions 5-7 made up 70%-85% of the total number of cells recovered. In chickens with acute disease symptoms, 85% of the cells from birds infected with JM-V lymphoblastic leukemia were found in fraction 4 and 50% of those from birds injected with MDV were recovered in fraction 3 (ie, they were more buoyant). Peak numbers of rosette-forming B cells (RFC) in NS were found in fraction 3, whereas max mitogen-induced blastogenesis was detected in the cells of fraction 5. Fewer RFC were found in cells from JM-V-treated chickens, and marked inhibitory effects of mitogens were noted in the buoyant fractions of JM-V and MDS cells. The data suggest that depressed T-cell reactivity in MDS and JM-V cells results from the selective depletion of mitogen-responsive T-cells. (8 refs)

79-5124 Expression of Marek's Disease Virus in Producer and Non-producer Lymphoblastoid Cell Lines. (Eng) Nazerian, K. (Science and Education Admin., Regional Poultry Res. Lab., U.S. Dept. Agriculture, E. Lansing, MI); Payne, W. S. *IARC Sci Publ* 24(11): 635-638; 1978.

Expression of the Marek's disease virus (MDV) genome was studied in two T-cell-derived lymphoblastoid lines (MSB-1 and RPL-1) established from MD tumors and in a B-cell-derived line (TLT-6855) established from an avian lymphoid leukemia tumor. Continuous in vitro propagation of the producer cell line MSB-1 reduced the number of cells producing MDV-related cellular and membrane antigens and the inducibility of these antigens with 5-iododeoxyuridine (IUDR), but it did not change the oncogenicity of the cells for chickens. In contrast, propagation of the nonproducer cell line RPL-1 did not change the nonproductivity of the cell line, but it decreased the transplantability of the cells. The MD lines were free of replicating avian leukosis/sarcoma viruses (LSV), and all three lines were susceptible to infection with LSV of subgroup A. (6 refs)

79-5125 Studies on Resistance to Marek's Disease Tumorigenesis: Effect of Immune Stimulation, Tumour-Cell Vaccines, and Herpesvirus of Turkeys

on Tumour Immunity. (Eng) Donahoe, J. P. (Ohio State Univ., Columbus, OH); Kleven, S. H.; Eidson, C. S. *IARC Sci Publ* 24(11): 1037-1041; 1978.

The effects of immune stimulation, tumor-cell vaccines, and herpesvirus of turkeys (HVT) on immunity of chickens to Marek's disease (MD) were studied. Inoculation of *Corynebacterium parvum* into MD-susceptible chicks did not enhance delayed hypersensitivity (DH) to tumor cells but increased DH to *C. parvum*. Birds vaccinated with the MSB-1 strain of MD tumor cells had significantly higher DH to tumor cells and a significantly lower incidence of mortality and MD lesions. Bursectomized birds were protected by MSB-1 vaccination. DH indices to MD cells were higher in birds vaccinated with HVT than in unvaccinated birds ($p < 0.1$). Absorption of anti-Marek's associated tumor surface antigen sera with HVT-infected cells caused no change in titer. The data indicate that nonspecific immune stimulation may be harmful to tumor resistance, that immune stimulation specific for tumor cells is beneficial, that cellular immunity is involved, and that HVT vaccination acts to stimulate specific cellular immunity against tumor cells. (8 refs)

79-5126 Neonatal Tumour Induction: The Emerging Immune Surveillance Mechanism and Amphibian Embryo Tumorigenesis. (Eng) Mizell, M. (Lab. Tumor Cell Biology, Tulane Univ., New Orleans, LA); McCue, R.; Charbonnet, L. *IARC Sci Publ* 24(11): 835-844; 1978.

Tumor induction in *Rana pipiens* larvae and froglets after inoculation of Lucke tumor herpesvirus (LTHV) during various developmental stages was studied. More than 50% of the animals inoculated during the three earliest stages [embryonic stage (S 20), larval stage (S 25), and early metamorphic stage (TK IV)] developed tumors. Some animals developed as many as four tumors. The majority of tumors resulting from inoculation of S 20 embryos were of the pronephric type, whereas the majority of the tumors resulting from inoculation of the S 25 and TK IV stages were of the mesonephric type. No tumors were induced when inoculation was delayed until after stage TK IV. At the time of inoculation, none of the early embryo/larvae groups had reached the stage of immunological competence during which IgG is produced. The older group, which developed no tumors, had reached immunological competence before inoculation. The relevance of these findings to tumor induction by Epstein-Barr virus is discussed. (10 refs)

79-5127 Genetics of Xenotropic Virus Expression in Mice. I. Evidence for a Single Locus Regulating Spontaneous Production of Infectious Virus in Crosses Involving NZB/BINJ and 129/J Strains of Mice.

(Eng) Levy, J. A. (Dept. Medicine, Cancer Res. Inst., Univ. California, San Francisco, CA 94143); Joyner, J.; Nayar, K. T.; Kouri, R. E. *J Virol* 30(3): 754-758; 1979.

The extent of infectious xenotropic (X-tropic) virus expression in homogenized splenic tissue from the high-virus-expressing NZB/BINJ mice and the non-virus-expressing 129/J mice and their crosses was examined by genetic analysis. The host range of this virus includes human, rat, mink, and dog cells. The data suggest that a single autosomal "dominantlike" gene controls the spontaneous production and release of infectious X-tropic virus in NZB mice. Analysis of infectious virus production in second-backcross families [(F₁ x 129) x 129] confirmed this conclusion. Variations in the amount of X-tropic virus released were evident in all genetic crosses. Virus titers (expressed as focus-forming units per milliliter) of supernatant fluid ranged from high levels in the NZB mice to somewhat lower levels in crosses involving the 129 mice. In the absence of a definite pattern in the titers observed in the genetic crosses studied, the term dominantlike is proposed for the single gene regulating the expression of X-tropic virus in NZB mice. (23 refs)

79-5128 The Effect of Ethidium Bromide on C Type Virus Production and Induction. (Eng) Avery, R. J. (Dept. Biological Sciences, Univ. Warwick, Coventry, CV4 7AL, England); Levy, J. A. *Virology* 95(2): 277-284; 1979.

The effect of ethidium bromide (EB: 0.1-1.0 µg/ml) on the production and induction, by 5-iododeoxyuridine (IUDR), of C-type murine leukemia virus (MuLV) from chronically infected BALB S + L- cells was studied. Production of both spontaneously released and induced virus was suppressed by EB, even at low concentrations. This inhibition was observed when EB was added before, 24 hr after, or together with IUDR, although the most pronounced effects were seen when EB was added before or with IUDR. The effect of EB apparently was not an indirect result of an inhibition of cell growth, and the dye had no substantial effect on cell viability or on the uptake of IUDR. EB lowered the production of infectious virus by a number of cell lines chronically producing a variety of MuLV's. The infectivity of the virus, but not the total production of virus particles or reverse transcriptase, was reduced from 3×10^5 to 3×10^4 focus-forming units/ml. The viability of rat K-NRK cells (producing Kirsten sarcoma and leukemia viruses) was not markedly impaired by EB treatment. (23 refs)

79-5129 An Interferon-sensitive Early Step in the Establishment of Infection of Murine Cells by Murine Sarcoma/Leukaemia Virus. (Eng) Morris, A. G. (Dept. Biological Sciences, Univ. Warwick, Coventry

CV47AL, England); Burke, D. C. *J Gen Virol* 43(part 1): 173-181; 1979.

NIH3T3 mouse cells were infected at very high multiplicity with murine sarcoma/leukemia virus (MSV/MLV) and then cloned. All of the 48 clones obtained were morphologically transformed, all but one showed anchorage-independence of growth, typical of MSV-transformed NIH3T3 cells and most (91%) produced MSV/MLV. When cells pre-treated with 10^4 units/ml of purified interferon (IF) were infected under the same conditions and then cloned in the presence of the same amount of IF, only 6/63 clones were morphologically transformed. The remaining clones showed a degree of anchorage-independence typical of the uninfected parental cells and very few (2.4%) produced virus. Furthermore, the MSV genome could not be rescued in any of the 23 clones tested and only 1/10 clones produced tumors. The properties of these clones remained stable over a period of 10 to 20 passages in the absence of interferon. It is concluded that interferon can irreversibly block an early step in the MSV/MLV infectious process. (21 refs)

79-5130 The Friend Virus Genome: Partial Characterization of a Complete DNA Copy. (Eng) Pragnell, I. B. (Beatson Inst. Cancer Res., Wolfson Lab. Molecular Pathology, Garscube Estate, Switchback Rd., Bearsden, Glasgow, G61 1BD, Scotland); Ostertag, W.; Paul, J.; Williamson, R. *J Gen Virol* 43(part 1): 1-14; 1979.

A complementary DNA probe has been prepared from the Friend murine erythroleukemia virus complex released by Friend cells [FV cDNA(D-)] and Friend cells induced to differentiate [FV cDNA(D+)]. Molecular hybridization analysis showed the following: (a) FV cDNA(D+) is close to being a complete copy of the virus genome, and the distribution of sequences is uniform with the distribution in the Friend virus genome. (b) Hybridization of 70S RNA from the cloned helper virus to the total FV cDNA(D+) probe demonstrates that a larger proportion of the cDNA is specific to the transforming spleen focus-forming virus. (c) Hybridization of the probe to normal and transformed cell DNA shows that there are about seven Friend virus-related genes in normal DNA and almost twice this amount in transformed cell DNA; a significant minor proportion (20%) of the cDNA probe anneals only to virus-related sequences in the transformed cell DNA. (d) An analysis of the kinetics of annealing of the cDNA to an excess template RNA shows that the minimum base sequence complexity of the Friend virus complex is 4×10^6 . (e) An analysis of the cross hybridization between FV cDNA(D+) and 60 to 70S RNA isolated from virus released by uninduced and induced cells shows that the genome of the induced and uninduced Friend virus is almost identical. (32 refs)

VIRAL CARCINOGENESIS

- 79-5131 Characterization of a Protein Found in Cells Infected with the Spleen Focus-forming Virus That Shares Immunological Cross-Reactivity with the gp70 Found in Mink Cell Focus-inducing Virus Particles. (Eng) Ruscetti, S. K. (Lab. Tumor Virus Genetics, NCI, Bethesda, MD 20014); Linemeyer, D.; Feild, J.; Troxler, D.; Scolnick, E. M. *J Virol* 30(3): 787-798; 1979.

An antigen detected in cells infected with spleen focus-forming virus (SFFV) by a radioimmunoassay specific for the gp70's of murine leukemia mink cell focus-inducing (MCF) viruses was characterized in competition radioimmunoassays with limiting dilutions of antibody and in pulse-labeling studies under conditions of antibody excess. Both methods of analysis indicated that the SFFV-encoded antigen is a glycoprotein with a mol wt of approx 52,000 daltons. The gp52 shared immunological reactivity and methionine-containing tryptic peptides with the gp70 of a Friend MCF virus and was expressed on the surface of SFFV-infected cells as well as in the cytoplasm. The gp52 could be detected in fibroblastic cell lines from several species when these cells were infected with SFFV, in several established erythroleukemic cell lines, and in the spleens of mice recently infected with SFFV. Although it shared immunochemical properties with the gp70 of Friend MCF virus, the gp52 could be distinguished from the MCF gp70 (1) by its apparent lack of group and interspecies immunological determinants, compared with MCF virus-derived gp70's; (2) by its failure to be released from cells infected with SFFV or SFFV plus helper virus; (3) by its mol wt; and (4) by tryptic peptide analysis. The results indicate that SFFV codes for an MCF gp70-related gp52 that is apparently no longer a virion structural protein like the MCF gp70 from which it was originally derived. (31 refs)

- 79-5132 Optimal Conditions for Synthesis of Long Complementary DNA Product with Moloney Murine Leukemia Virus. (Eng) Van Beveren, C. (Lab. Physiological Chemistry, Univ. Leiden, 2333 AL Leiden, Netherlands); Goulian, M. *J Virol* 30(3): 951-954; 1979.

The interrelationships between divalent metals, deoxynucleotide triphosphates (dNTP's), and PP_i in determining the properties of the complementary DNA (cDNA) product from the in vitro reverse transcriptase reaction with detergent-treated Moloney murine leukemia virus were studied. In spite of the severalfold greater amount of cDNA product with Mn²⁺ than with Mg²⁺, the net yield of high-mol-wt cDNA was much greater with Mg²⁺ than with Mn²⁺. This held true, as well, for the reactions containing excess dNTP or dNTP plus PP_i, both of which (as has been reported for Mg²⁺) promote synthesis of the high-mol-wt cDNA product. A high total dNTP concentration remained important for a max high-mol-wt product with Mg²⁺, and it was not replaced by simply providing dNTP in excess over Mg²⁺. Under the conditions tested, the addition of PP_i did not further increase the cDNA product size with Mg²⁺

when compared with dNTP in excess over Mg²⁺. The extent of degradation of the RNA template during the incubations was correlated with the size of the cDNA product. (18 refs)

- 79-5133 Multiple Integration Sites for Moloney Murine Leukemia Virus in Productively Infected Mouse Fibroblasts. (Eng) Bacheler, L. T. (Tumor Virology Lab., Salk Inst., San Diego, CA 92112); Fan, H. *J Virol* 30(3): 657-667; 1979.

The integration sites for viral DNA in mouse 3T6 cells infected with Moloney murine leukemia virus (M-MuLV) were studied by restriction endonuclease cleavage of cellular DNA followed by electrophoresis in agarose gels, blot transfer to nitrocellulose, and detection of M-MuLV-related sequences by hybridization with high-specific-activity ³²P-labeled M-MuLV complementary DNA. When *EcoRI* was used to cleave cellular DNA, numerous DNA fragments with sequence homology to M-MuLV were detected in uninfected mouse cell DNA. These endogenous sequences are mouse specific, since they were not detectable in rat cell DNA and they were found to be related to the 38S genomic RNA of M-MuLV. Infected cells contained additional M-MuLV-specific DNA fragments that were not detected in uninfected cells. Different patterns of M-MuLV-specific DNA fragments were detected in each cloned infected line examined. These data suggest that there are multiple sites for the integration of M-MuLV DNA in infected mouse fibroblasts. Cleavage of infected cell DNA with *BamHI*, which cleaves M-MuLV viral DNA at least twice, released the internal *BamHI* B fragment from each infected line, confirming the presence, in each infected cell line, of integrated M-MuLV DNA sequences that retain some features of the sequence organization of unintegrated M-MuLV DNA. (22 refs)

- 79-5134 The Isolation and Preliminary Characterization of Temperature-sensitive Transformation Mutants of Moloney Sarcoma Virus. (Eng) Blair, D. G. (Lab. Viral Carcinogenesis, Building 41, Suite 400, NCI, Bethesda, MD 20205); Hull, M. A.; Finch, E. A. *Virology* 95(2): 303-316; 1979.

The isolation and preliminary characterization of temperature-sensitive (*ts*) transformation mutants of Moloney murine sarcoma virus (MSV) are described. The mutants were isolated from UV-irradiated viral stocks using a selection and screening procedure based on the ability of MSV-transformed normal rat kidney cells to grow in methylcellulose or agar suspension. Mutants isolated by this procedure formed colonies in agar 1,000- to 10,000-fold more efficiently at 34 C than at 39 C. They also exhibited a transformed morphology and elevated hexose transport levels at 34 C, but they were phenotypically normal at 39 C. Both morphology and hexose transport showed transformed-to-normal and normal-to-transformed

conversion within 12-48 hr of a temperature shift from 34 to 39 C and 39 to 34 C, respectively. In contrast, *ts*-transformed cells suspended in agar and incubated at 39 C for 24 hr showed a 90% reduction in colony-forming ability when the plates were returned to 34 C. Superinfection of nonproducer *ts*-transformed cells with leukemia virus resulted in the rescue of *ts* MSV. Rescued supernatants also contained a high proportion (10%) of wild-type (*wt*) MSV. Repeated cloning of *ts* mutants, either as virus or cells, did not significantly affect the proportion of *ts* or *wt* virus rescued. The ability of *ts*-transformed cells to express the transformed phenotype at 39 C could be restored by *wt* MSV superinfection, but not by murine leukemia virus superinfection. (33 refs)

- 79-5135 Type C RNA Virus Proteins: Lack of Binding Specificity to Host Cell Chromosomal DNA In Vitro. (Eng) Miles, K. (Dept. Pathology, Univ. Chicago, Chicago, IL 60637); Schwartz, S. A. *Exp Cell Biol* 47(2): 81-91; 1979.

The C-type virus protein:eukaryote DNA interaction was examined in vitro to determine whether this regulatory mechanism plays a significant role in the control of RNA tumor virus expression in rat cells. Two different DNA-protein reconstitution methods were used. Rauscher murine leukemia virus, purified from chronically infected rat cell cultures, was iodinated in vitro with ¹²⁵I and dissociated in a nondetergent, high-ionic-strength, urea-containing buffer. The chemically separated ¹²⁵I labeled viral polypeptides were reconstituted with purified DNA by affinity column chromatography and by gradient dialysis renaturation. In both instances, no detectable amount of radioactivity specifically bound to double-stranded DNA of any origin. This observation contrasted with the binding behavior of identically prepared and radiolabeled nonhistone chromosomal proteins purified from rat cell nuclei. This finding may rule out, in eukaryote cells, a well-described prokaryotic regulatory mechanism for the control of integrated viral gene expression. (29 refs)

- 79-5136 Potentiation of Leukemogenicity and Infectivity of Rauscher Leukemia Virus by an Enhancing Factor Present in Egg Fluids. (Eng) Gazit, A. (Dept. Human Microbiology, Sackler Sch. Medicine, Tel-Aviv Univ., Ramat-Aviv, Tel-Aviv, Israel); Eylan, E.; Rosen, N.; Samucha, R. *Exp Cell Biol* 47(1): 29-42; 1979.

These studies demonstrate that the resistance of adult mice to Rauscher leukemia virus (RLV) infection is partially counteracted by sequential ip administration of a low-mol-wt enhancing factor from chicken egg fluids. Sequential ip administration of this factor to BALB/c mice infected with RLV significantly stimulated viral replication, as evidenced by elevated viral DNA polymerase levels in mouse sera.

This stimulation of viral replication correlated with an aggravation of viral leukemogenicity that was reflected by an increased splenomegaly response and a reduction of survival time. The in vivo potentiation of RLV replication and leukemogenicity by the enhancing factor was achieved at least partly at the cellular level, since RLV replication was also stimulated in an in vitro system. It is assumed that the stimulatory effect of the enhancing factor on viral replication is connected with its stimulatory effect on cellular DNA synthesis. (26 refs)

- 79-5137 Depression of Rauscher Leukemia Virus Envelope Glycoprotein gp71 Binding by Lymphoid Cells During Leukemogenesis in Mice. (Eng) Fowler, A. K. (Carcinogenesis Intramural Program, NCI Frederick Cancer Res. Center, NIH, Frederick, MD 21701); Reed, C. D.; Riggs, C. W.; Twardzik, D. R.; Weislow, O. S.; Hellman, A. *Infect Immun* 24(3): 647-655; 1979.

The availability of membrane receptors for the 71,000-dalton envelope glycoprotein (gp71) of Rauscher murine leukemia virus on splenic and thymic cells from BALB/c mice during Rauscher murine leukemia virus-induced leukemogenesis was determined by a radiolabeled gp71 binding assay. Shortly after infection, the relative cellular [¹²⁵I]gp71 binding level decreased, first with splenic cells (at days 7-10 after infection) and later with thymic cells (at days 10-20 after infection). The dependency of the reduction of binding on the replication of the inoculated virus was demonstrated by regression analyses using the cellular gp71 binding level as the dependent variable and the infectious virus titer, as well as viral gp71 and p30 levels, of spleens and thymuses from infected mice as independent variables. With each independent variable, the reduction of gp71 binding for both cell types was highly dependent ($p < 0.01$) on the level of virus detected in their respective organ. In the early stages of leukemogenesis, the [¹²⁵I]gp71 binding level declined to approx 20%-30% of control values. During this period, the rate of reduction of binding was very rapid and, in general, was similar for both splenic and thymic cells. Further progression of the disease resulted in little or no further reduction in binding. This technique may be used to monitor host ecotropic virus synthesis and to study cell-surface virus receptor control mechanisms in vivo. (34 refs)

- 79-5138 Fragility of Attenuated Rauscher Leukemia Virus. (Eng) Barbieri-Weill, D. (Laboratoire de culture de tissus, Institut Gustave-Roussy, Villejuif, France); Leibovitch, S. A.; Athan, E.; Emanoil-Ravicovitch, R.; Harel, J. *Intervirology* 11(6): 326-332; 1979.

A previous study showed that attenuated (RCL-) Rauscher leukemia virus (RLV) was 100 times less infectious in vitro

than virulent (RRL+) RLV and that its leukemogenicity was almost abolished. An attempt was made to correlate these differences in biological properties with some biochemical defect of RCL-. After centrifugation, the amount of reverse transcriptase (RT) activity in aged RCL- (collected 18-24 hr after the medium was changed) was only 25%-30% of that in aged RRL+. When each virus was further centrifuged to equilibrium in a sucrose gradient, no more than 10% of the initial RT activity of aged RCL- was found at the density of intact virions (1.14-1.16 g/cm³), and no visible band could be seen in this zone. In contrast, almost all the initial RT activity of aged RRL+ was found in a visible band. The thermal sensitivity of the RT of both viruses was the same. A 60S-70S RNA could be extracted from aged RRL+, but no high-mol-wt RNA was obtained from aged RCL-. The fragility seemed to increase during aging, as both fresh RCL- (collected after 1-6 hr) and fresh RRL+ banded at 1.14 g/cm³, and high-mol-wt RNA could be extracted from fresh RCL-. Molecular hybridization studies showed that 20% of the nucleic acid sequences related to RLV found in the RNA of RRL+-infected cells were missing in the RNA of cells infected with RCL-. Whatever the role of aging, it seems probable that an intrinsic fragility of RCL- is responsible for the attenuation of its infectivity and leukemogenic potency. (18 refs)

- 79-5139 Analysis of Proteins of Mouse Sarcoma Pseudotype Viruses: Type-specific Radioimmunoassays for Ecotropic Virus p30's. (Eng) Kennel, S. J. (Biology Div., Oak Ridge Natl. Lab., Oak Ridge, TN 37830); Tennant, R. W. *J Virol* 30(3): 729-734; 1979.

A type-specific radioimmunoassay for ecotropic virus p30's was developed to analyze the proteins of murine sarcoma virus pseudotype viruses. The pseudotypes were prepared by the infection of nonproducer cells (A1-2), which were transformed by the Gazdar strain of mouse sarcoma virus, with Gross (N-tropic), WN1802B (B-tropic), or Moloney (NB-tropic) viruses. The respective host range pseudotype sarcoma viruses were defined by their titration characteristics on cells with the appropriate *Fv-1* genotype. Proteins from virus progeny were analyzed by sodium dodecyl sulfate-polyacrylamide gel electrophoresis. Bands present in both the 65,000- and the 10,000- to 20,000-mol-wt regions of the gel distinguished the pseudotype viruses from their respective helpers. Furthermore, two protein bands were noted in the p30 region of murine sarcoma virus (Gross), one corresponding to Gross virus p30 and another of slightly slower mobility. However, since the mobility of the putative sarcoma p30 is nearly identical to that of WN1802B, its presence could not be established by sodium dodecyl sulfate-polyacrylamide gel electrophoresis. Type-specific radioimmunoassays for Gross virus p30 and for WN1802B p30 were used to analyze pseudotype preparations, and among several ecotropic viruses tested, only the homologous virus scored in the respective assay. These assays showed that pseudotype viruses contain only

8%-48% helper-specific p30's; the remainder is presumably derived from the sarcoma virus. (18 refs)

- 79-5140 Establishment of Cell Lines from the Wild Rodent *Millardia meltdada* and Tests for Endogenous Virus. (Eng) Sugiyama, H. (Dept. Tumor Viruses, Res. Inst. Microbial Diseases, Osaka Univ., Yamada-kami, Suite 565, Japan); Yutsudo, M.; Toyoshima, K.; Yosida, T. H.; Murata, Y. *Gann* 70(3): 297-303; 1979.

Four cell lines were established from the wild rodent *Millardia meltdada*: an untransformed cell line (MM-D), a nonproducer (NP) cell line transformed by murine sarcoma virus (MM-CL4), and two simian virus 40 (SV40)-transformed cell lines (MM-8, MM-663). MM-D was epithelioid and contact-inhibited, whereas MM-CL4, MM-8, and MM-663 were fibroblastic and showed piling-up behavior. No endogenous virus was induced in *Millardia* cell lines by a long-term culture with various inducers. *Millardia* cell DNA had no nucleotide sequence homology with complementary DNA of either murine leukemia virus or rat endogenous virus. (24 refs)

- 79-5141 Characterization of a Defective Pseudotype Particle of Kirsten Sarcoma Virus. (Eng) Myerson, D. (Dept. Molecular Biology, Albert Einstein Coll. Medicine, Bronx, NY 10461); Scheinberg, D.; Klement, V.; Strand, M.; August, J. T. *Virology* 95(2): 536-549; 1979.

The composition of pseudotype particles of Kirsten sarcoma virus (Ki-SV) rescued from normal rat kidney (NRK) cells by superinfection with woolly monkey leukemia virus (WLV) was analyzed. A cell line was isolated that produces a defective pseudotype particle of Ki-SV without detectable infectious helper virus. NRK cells were infected at low multiplicity with a virus stock obtained by the rescue of Ki-SV with WLV. The individual transformed cell foci that resulted were propagated. One was found to produce noninfectious oncovirus particles containing high reverse transcriptase activity. These defective particles contained an active sarcoma genome but no detectable helper virus genome, as cells fused to the particles became transformed but did not show evidence of helper WLV expression. Nevertheless, the NRK cells producing the defective particles contained the complete WLV genome; after prolonged culture, infectious WLV's were released and rapidly spread through the culture. The defect of the noninfectious particle could be attributed to the absence of the viral envelope glycoprotein. Helper virus *env* gene products were not detected in cells producing the defective particle, and these cells did not exhibit interference to superinfection by WLV. The protein composition of the defective particle was unusual. Major proteins were a WLV p28 and a novel

55,000-dalton protein of rodent origin. The latter was not immunologically related to the known rodent C-type virus *gag* or *env* gene products; nevertheless, it was immunoprecipitated by several anti-murine leukemia virus sera, suggesting that a related protein is commonly present in preparations of purified mouse C-type viruses. (42 refs)

- 79-5142 Induction of Lytic Plaques by Murine Leukemia Virus in Murine Sarcoma Virus-transformed Nonproducer Mouse Cells Persistently Infected with Mouse Hepatitis Virus MHV-S. (Eng) Yoshikura, H. (Dept. Genetics, Inst. Medical Science, Univ. Tokyo, PO Takanawa, Tokyo, Japan); Taguchi, F. *Intervirology* 11(2): 69-73; 1979.

The induction of lytic plaques by murine leukemia virus (MuLV) in cultures persistently infected (PI) with mouse hepatitis virus strain S (MHV-S) is reported. Kirsten murine sarcoma virus-transformed, nonproducer BALB3T3 (K-BALB) cells were PI with MHV-S at a multiplicity of infection (MOI) of about 1. The growth rate of these cells (termed MHV-KB) and the culture morphology were hardly affected by the infection. To determine whether there is an interaction between MHV-S and MuLV in the PI cultures, the MHV-KB cells were superinfected with Abelson MuLV at an MOI of 0.1. After 3-4 days, many giant cells appeared in the MuLV-infected cultures, and massive cytolysis finally resulted. The giant cells appeared when MuLV production began. In spite of the cytological changes produced by the MuLV, the MHV-S titers in the medium were similar for MuLV- and mock-infected cultures. If the MuLV inoculum was diluted serially and used to infect MHV-KB cells, plaques consisting of giant cells appeared in proportion to virus dose. When the MuLV-infected cultures were further submitted to the UV XC assay, comparable numbers of XC plaques were obtained. As a control, K-BALB cells were infected with MuLV. No giant cells appeared, and, in the UV XC assay, a significantly higher titer of MuLV was obtained in MHV-KB cells than in K-BALB cells. (19 refs)

- 79-5143 Inhibition of Murine Sarcoma Virus-induced Foci Formation by Cytidine Analogues and Other Drugs Chemotherapeutically Effective in Human Malignancies. (Eng) Wan, C. W. (Ontario Cancer Inst., 500 Sherbourne St., Toronto M4X 1K9, Canada); Mak, T. W. *Intervirology* 11(5): 291-299; 1979.

The antiviral activities of 12 commonly used chemotherapeutic drugs were tested using the Kirsten murine sarcoma virus transformation focus assay. The plating efficiencies of the cells treated with the drugs were monitored simultaneously. Only the cytidine analogs--cyclocytidine, 1- β -D-arabinofuranosylcytosine (ara-C), and azacytidine--showed a selective effect on inhibition of

viral foci over cytotoxicity. With ara-C, an exposure time of 10-30 hr produced the most pronounced effect on the inhibition of foci formation over that of cytotoxicity. (34 refs)

- 79-5144 Murine Sarcoma Viruses Block Corticosteroid-induced Differentiation of Bone Marrow Preadipocytes Associated with Long-Term In Vitro Hemopoiesis. (Eng) Greenberger, J. S. (Joint Center Radiation Therapy, 50 Binney St., Boston, MA 02115); Davisson, P. B.; Gans, P. J. *Virology* 95(2): 317-333; 1979.

The effects of the Harvey, Kirsten, and Moloney strains of murine sarcoma virus (MSV) infection of NIH/Swiss and BALB/c mouse bone marrow preadipocytes on adipocyte differentiation and hemopoiesis were studied. MSV blocked adipocyte differentiation in whole marrow cultures, decreased the numbers of biologically active colony-forming hemopoietic cells, and increased the proliferating adherent cell compartment. The effect on adipocytes was detected earlier than that on hemopoiesis. The individual bone marrow preadipocytes showed a corticosteroid dependence for differentiation in vitro. MSV prevented differentiation of preadipocytes to colony-forming unit adipocytes (CFUa) under conditions which did not inhibit differentiation of granulocyte-macrophage progenitor cells. CFUa at 14 days after MSV infection released RNA type-C virus with host range identical to that of the input virus. An MSV-specific block of both CFUa formation and insulin-dependent differentiation of the 3T3-L1 embryo preadipocyte cell line was also detected by 14 days. (44 refs)

- 79-5145 Cell Surface Expression of the *env* Gene Polyprotein of Dual-tropic Mink Cell Focus-forming Murine Leukemia Virus. (Eng) Famulari, N. G. (Memorial Sloan-Kettering Cancer Center, New York, NY 10021); Jelalian, K. *J Virol* 30(3): 720-728; 1979.

The virus-host interaction of mink cell focus-forming (MCF 247) murine leukemia virus was studied in mouse and mink fibroblasts to determine whether any unusual features of protein processing exist. Emphasis was placed on the processing of the *env* gene products. Differences were observed in the kinetics of processing of the *env* gene polyprotein of ecotropic, xenotropic, and dual-tropic MCF murine leukemia virus. In pulse-chase experiments, the *env* gene polyprotein of the dual-tropic MCF virus exhibited a marked increase in stability relative to that of the ecotropic or xenotropic virus. A comparison was made of the cell-surface expression of *env* gene products of ecotropic, xenotropic, and dual-tropic MCF murine leukemia virus. Only gp70 was accessible to lactoperoxidase-catalyzed radioiodination of fibroblasts infected by ecotropic or

kenotropic virus, whereas both gp70 and the *env* gene polyprotein were expressed on the surface of dual-tropic MCF virus-infected cells. (35 refs)

79-5146 Nucleotide Sequence of the Self-priming 3' Terminus of the Single-stranded DNA Extracted from the Parvovirus Kilham Rat Virus. (Eng) Salzman, L. A. (Lab. Biology Viruses, Natl. Inst. Allergy and Infectious Diseases, NIH, Bethesda, MD 20014); Fabisch, P. *J Virol* 30(3): 946-950; 1979.

The parvovirus genome is a linear, single-stranded DNA molecule with double-stranded hairpin termini. The 3' terminus can serve in vitro as a self-primer for the synthesis of a double-stranded viral DNA intermediate. A sequence analysis was made of the nucleotides in the 3' terminus of the single-stranded DNA extracted from the autonomous parvovirus Kilham rat virus, and a model is proposed for the secondary structure of the terminus and the in vitro origin of replication for the complementary viral DNA strand. The data do not allow any final conclusions as to the functional role of all parts of the 3' DNA terminus. They do, however, confirm the probability of a highly structured terminal sequence that is capable of folding back on itself and forming a hairpin turn. This hairpin-shaped, double-stranded DNA could serve as the self-primer for initiation of the viral double-stranded replicative intermediate. (21 refs)

79-5147 Biochemical and Immunological Properties of the Reverse Transcriptase Associated with a Hamster Retrovirus. (Eng) Gregerson, D. S. (Dept. Ophthalmology and Visual Science, Yale Univ. Sch. Medicine, New Haven, CT); Russell, P.; Reid, T. W. *J Gen Virol* 43(2): 327-337; 1979.

An RNA-directed DNA polymerase associated with a hamster retrovirus (HaRV) was characterized. The enzyme is similar to other polymerases from mammalian type-C viruses in that it is more active with Mn^{2+} than Mg^{2+} , uses the reverse transcriptase-specific poly(rCm).oligo(dG) template, possesses substantial endogenous polymerase activity, and is strongly inhibited by homologous antisera and moderately inhibited by antisera against other type-C viruses. In contrast to previous reports of polymerases from other hamster viruses, HaRV polymerase is active in endogenous assays and the activity is associated with a 70,000 mol wt polypeptide in highly purified virions and with 70,000- and 85,000 mol wt polypeptides in fresh, unpurified virus. Only one major peak of polymerase activity eluted from 2-(diethylamino)ethanol-cellulose, but the subsequent elution of this peak from phosphocellulose produced two major peaks of polymerase activity. The mol wt of these two peaks were 70,000 and 85,000 by glycerol density-gradient sedimentation. Antigenically, the HaRV

reverse transcriptase and p30 antigen were most closely related to other rodent retrovirus proteins. (21 refs)

79-5148 Characteristics of a Retrovirus Associated with a Hamster Melanoma. (Eng) Russell, P. (Dept. Ophthalmology and Visual Science, Yale Univ. Sch. Medicine, New Haven, CT); Gregerson, D. S.; Albert, D. M.; Reid, T. W. *J Gen Virol* 43(2): 317-326; 1979.

The continuous culture of a hamster melanoma cell line has led to the spontaneous appearance of a retrovirus (HaRV) with typical type-C characteristics. The virus differs from all other known hamster viruses in its ability to transform murine as well as rat and hamster cells with apparent one-hit kinetics. Guinea pig, human and feline cells were not transformed although reverse transcriptase activity was detected in the supernatant from infected human cells. HaRV-transformed hamster embryo cells produced solid tumors (all nonpigmented) in 4/35 animals when injected into hamsters, but HaRV-transformed murine cells produced no tumors in mice. Injection of HaRV alone in hamsters, mice, and rabbits did not induce tumors. HaRV possesses a 70S RNA that dissociates to 35S in dimethyl sulfoxide, and it has a reverse transcriptase that uses the 70S virus RNA as a template. The size, morphology, and density (1.15 g/ml) are similar to other known type-C viruses. Polyacrylamide gel electrophoresis indicated the presence of polypeptides analogous to those found in other type-C viruses. (24 refs)

79-5149 The Interaction Between Herpesvirus and Oncornavirus of Guinea Pigs: In Vitro and In Vivo Studies. (Eng) Fong, C. K. (Virology Lab., Veterans Admin. Hosp., West Haven, CT); Hsiung, G. D. *IARC Sci Publ* 24(11): 981-989; 1978.

Cultured guinea pig embryo cells doubly infected with guinea pig herpeslike virus (GPHLV) and guinea pig oncornavirus (GPOV) contained pseudotype virus particles with an oncornavirus morphology that were coated with GPHLV antigen, as detected by immunoferritin electron microscopy. Infection of Hartley guinea pigs with both GPHLV and GPOV induced lymph node hyperplasia in a higher percentage of animals than infection with either virus alone. In addition, infection of strain 2 guinea pigs with exogenous GPHLV delayed the development of L₂C leukemia in these animals. (13 refs)

79-5150 Multiple Copies of Shope Virus DNA Are Present in Cells of Benign and Malignant Non-Virus-producing Neoplasms. (Eng) Stevens, J. G. (Dept. Microbiology and Immunology, Sch. Medicine, Univ. California at Los Angeles, Los Angeles, CA 90024); Wetts-stein, F. O. *J Virol* 30(3): 891-898; 1979.

Qualitative and quantitative determinations were made of the extent to which the Shope papilloma virus genome is present in non-virus-producing benign and malignant tumors in domestic rabbits was established. With the use of nick-translated radioactive viral DNA purified from productively infected papillomas on cottontail rabbits as a probe, it was found that (1) papillomas, primary carcinomas, and metastatic carcinomas containing 10 to about 100 copies of the viral genome per diploid cell equivalent of DNA and (2) viral DNA is present in detectable amounts in essentially all neoplastic cells. These results are consistent with the suggestion that the continued presence of the viral genome is necessary for the induction and maintenance of malignant as well as benign neoplasms. (29 refs)

- 79-5151 Nature and Distribution of Feline Sarcoma Virus Nucleotide Sequences. (Eng) Frankel, A. E. (Dept. Medicine, Stanford Univ., Stanford, CA 94305); Gilbert, J. H.; Porzig, K. J.; Scolnick, E. M.; Aaronson, S. A. *J Virol* 30(3): 821-827; 1979.

The genomes of three independent isolates of feline sarcoma virus (FeSV), the Snyder-Theilen (ST), Gardner-Arnstein (GA), and McDonough and coworkers (SM) strains, were compared by molecular hybridization techniques. Using complementary DNA's (cDNA's) prepared from two strains, SM- and ST-FeSV, cDNA's were selected by sequential hybridization to FeSV and feline leukemia virus RNA's. These DNA's were shown to be highly related among the three independent sarcoma virus isolates. FeSV-specific cDNA's were prepared by selection for hybridization by the homologous FeSV RNA and against hybridization by feline leukemia virus RNA. Sarcoma virus-specific sequences of SM-FeSV differed from those of the ST- or GA-FeSV strains, whereas ST-FeSV-specific DNA shared extensive sequence homology with GA-FeSV. Molecular hybridization showed that, each set of FeSV-specific sequences was present in normal cat cellular DNA in approx one copy per haploid genome and that it was conserved throughout Felidae. In contrast, FeSV-common sequences were present in multiple DNA copies and were found only in Mediterranean cats. These results are consistent with the concept that each FeSV strain has arisen by a mechanism involving recombination between feline leukemia virus and cat cellular DNA sequences, the latter being represented within the cat genome in a manner analogous to that of a cellular gene. (34 refs)

- 79-5152 Sarcoma Virus-induced Transformation Specific Antigen: Presence of Antibodies in Cats That Were Naturally Exposed to Leukemia Virus. (Eng) Sliski, A. H. (Lab. Viral Carcinogenesis, NCI, Bethesda, MD 20014); Essex, M. *Virology* 95(2): 581-586; 1979.

A study was conducted to determine how often cats mount an immune response to FOCMA-S, a transformation-specific antigen believed to be encoded by the feline sarcoma virus (FeSV). Healthy cats that were naturally exposed to feline leukemia virus (FeLV) were examined for the presence of antibodies to FOCMA-S. Anti-FOCMA sera obtained from cats that were viremic with FeLV had analogous end point titers whether tested on FeLV-transformed nonproducer mink fibroblasts or cat lymphoma cell lines productively infected with FeLV. These results suggest that FOCMA-S shares at least one major antigenic determinant with FOCMA-L, which is expressed on lymphoma cells. (19 refs)

- 79-5153 On the Etiological Role of Herpesvirus Ovis in Jaagsiekte. (Eng) Verwoerd, D. W. (Molecular Biology Section, Veterinary Res. Inst., Onderstepoort, S. Africa); De Villiers, E. M.; Coetzee, S. *IARC Sci Publ* 24(II): 869-873; 1978.

The involvement of a herpesvirus (JS-3) in the etiology of jaagsiekte in sheep was studied. Neutralizing antibodies against JS-3 were found in 70% of 400 normal sheep, but only 50% of tumor-bearing sheep with jaagsiekte had antibodies against JS-3. The intratracheal injection of line 15.4 tumor cells derived from a sheep with jaagsiekte into newborn lambs resulted in jaagsiekte in 21/42 animals. Injection of tumor cell homogenates led to the disease being transmitted to 2/8 animals. The disease did not develop in animals inoculated with a tumor DNA extract or with JS-3 virus. In one case, the injection of male 15.4 cells into a female lamb resulted in a tumor with a female karyotype. Hybridization studies with JS-3 virus complementary RNA and DNA from 15.4 cells and jaagsiekte-positive and -negative biopsies showed no evidence for the presence of JS-3 virus genomes in any of these cells. Experimental evidence indicates the involvement of a latent viral genome in the etiology of jaagsiekte, but no conclusive evidence implicating herpesvirus ovis has been found. The possibility of a cocarcinogenic role in conjunction with a C-type RNA tumor virus should be investigated. (7 refs)

- 79-5154 Phosphonoformate Inhibition of Visna Virus Replication. (Eng) Sundquist, B. (Dept. Virology, Faculty Veterinary Medicine, Univ. Agricultural Sciences, Biomedical Center, S-751 23 Uppsala, Sweden); Larner, E. *J Virol* 30(3): 847-851; 1979.

Visna virus was used as a model system to study the inhibition of retrovirus replication by phosphonoformate (PFA). PFA inhibited visna virus replication in sheep choroid plexus cells; a 50% reduction in virus yield was obtained by 20 to 80 μ M PFA. [The discrepancy between the two values (20 and 80 μ M) is probably due to fluctuations involved in the end point titration method.] Morphological changes,

such as syncytia formation and cell degeneration, were reversibly prevented by PFA. Cell growth was not significantly affected by exposure to 500 μ M PFA through five passages, but treatment with 2 mM PFA did arrest cell growth after two to three passages. Cell-free reverse transcriptase activity primed with various synthetic template-primers was inhibited about 90% in the presence of 100 μ M PFA. The results of kinetic experiments suggested that reverse transcriptase was utilized early but not late in the infection cycle. A structurally related substance, phosphonoacetate, did not inhibit visna virus multiplication and had no inhibitory effect on reverse transcriptase activity at a concentration of 500 μ M. (14 refs)

- 79-5155 Transcription of the Bovine Parvovirus Genome in Isolated Nuclei. (Eng) Patton, J. T. (Dept. Biology, Virginia Polytechnic Inst., Blacksburg, VA 24061); Stout, E. R.; Bates, R. C. *J Virol* 30(3): 917-922; 1979.

Nondefective bovine parvovirus (BPV) was used to examine the effects of infection on RNA polymerase activities in nuclei isolated from synchronized bovine fetal spleen cells. The relative levels of total RNA polymerase and RNA polymerase I, II, and III activities in nuclei isolated from BPV-infected and mock-infected cells were similar throughout the course of infection. Hybridization of RNA synthesized in isolated nuclei indicated that BPV-specific RNA synthesis began 8-12 hr postinfection and proceeded linearly until at least 20 hr postinfection. By 20 hr postinfection, 5% of the total RNA synthesis in nuclei from infected cells was virus-specific. BPV-specific RNA synthesis was inhibited by 95% in the presence of 0.1 μ g/ml α -amanitin, suggesting that the viral genome is transcribed by cellular RNA polymerase II. (23 refs)

- 79-5156 Hybridization of Bovine Papilloma Virus Type 1 and Type 2 DNA to DNA from Virus-induced Hamster Tumors and Naturally Occurring Equine Tumors. (Eng) Lancaster, W. D. (Div. Otolaryngology, Case Western Reserve Univ., Cleveland, OH 44106); Theilen, G. H.; Olson, C. *Intervirology* 11(4): 227-233; 1979.

DNA's from bovine papilloma virus (BPV)-induced hamster tumors and from equine connective tissue tumors of unknown etiology were examined for BPV DNA sequences by molecular hybridization. DNA from two distinct classes of BPV (type 1 and type 2) was labeled in vitro and used as probes. Analysis of DNA-DNA reassociation kinetics indicated that both virus types were capable of tumor induction in the hamster. DNA isolated from 6/7 equine tumors accelerated the reassociation of the BPV DNA probes. BPV type 1 or type 2 DNA hybridized extensively to DNA from three tumors, but three other tumors

contained DNA sequences to which only a portion of the probes hybridized. Partial hybridization of probe DNAs to tumor DNA suggested the possible existence of a third BPV class. (19 refs)

- 79-5157 The Characterization of Mason-Pfizer Monkey Virus-induced Cell Fusion. (Eng) Chatterjee, S. (Dept. Microbiology, Univ. Alabama in Birmingham, Medical Center, Birmingham, AL 35294); Hunter, E. *Virology* 95(2): 421-433; 1979.

The characteristics and requirements of multinucleate cell (MNC:syncytium) induction by Mason-Pfizer monkey virus (M-PMV) in human and nonhuman primate cells were investigated. MNC induction by this D-type retrovirus showed single-hit kinetics on human foreskin and rhesus monkey fetal lung cells. The peak of syncytium-forming activity in an isopycnic sucrose gradient coincided with the peak of M-PMV virions, as assessed by electron microscopy and analysis of viral polypeptides. Unlike the paramyxoviruses, M-PMV did not induce "early" cell fusion when added in high concentrations to the target cells. Furthermore, MNC formation was max 48 hr postinfection, and the size of the syncytia remained constant after this time. UV irradiation of M-PMV reduced its ability to form syncytia and to replicate with single-hit kinetics, suggesting that a functional viral genome is required for syncytium formation. Proviral DNA synthesis and assembly of virions were not necessary for cell fusion, since the addition of cytosine arabinoside at concentrations that block virus replication had little effect on MNC formation. Moreover both MNC's lacking detectable intracellular virus polypeptides, and groups of individual, nonfused, but brightly staining cells could be observed in immunofluorescence assays at times when MNC formation was max. Cell fusion was inhibited by the addition of cycloheximide during the first 12 hr of infection, suggesting that de novo protein synthesis is required for MNC formation. The possibility that translation of genomic RNA yields a fusion-inducing product is discussed. (32 refs)

- 79-5158 Immunosuppression Reactivates and Disseminates Latent Murine Cytomegalovirus. (Eng) Jordan, M. C. (Div. Infectious Diseases, Dept. Medicine, Univ. California Sch. Medicine, Los Angeles, CA); Shanley, J. D.; Stevens, J. G. *IARC Sci Publ* 24(II): 769-774; 1978.

The reactivation of murine cytomegalovirus (MCMV) by immunosuppressive techniques was studied in C3H mice. By 4 wk after MCMV inoculation (1,000 plaque-forming units sc), virus was detected only in salivary gland tissue. After 21 days of treatment with rabbit antiserum prepared against murine lymphocytes (ALS), 11/24 mice developed active MCMV infection of the salivary glands and 3/12

developed active infection of the spleen. Reactivation of MCMV infection was achieved in virtually all mice by treatment with ALS plus cortisone acetate (125 mg/kg/day, ip). Among immunosuppressed mice, MCMV infection was widespread and viremia was documented. In unmanipulated mice, the virus appeared to be maintained in a latent state. Attempts to transfer MCMV infection by inoculation of uninfected mice with spleen cells from latently infected mice were unsuccessful. (12 refs)

- 79-5159 Lymphocyte Transformation and Interferon Production as Measures of Cellular Immunity in Lymphoma Patients. (Eng) Arvin, A. M. (Div. Infectious Diseases, Stanford Univ. Sch. Medicine, Stanford, CA); Pollard, R. B.; Rasmussen, L. E.; Rand, K. H.; Merigan, T. C. *IARC Sci Publ* 24(II): 745-751; 1978.

Lymphocyte transformation and interferon production to varicella zoster virus (VZV) were evaluated in 45 untreated lymphoma patients, 35 lymphoma patients who had been in remission for at least 2 yr, and 42 normal VZV-immune subjects. Lymphocyte transformation by VZV antigen did not occur in 44% of the treated subjects, 12/35 patients in remission, and 9% of the normal subjects. There was no detectable interferon production to VZV antigen in 32% of the untreated patients and 4.8% of the controls, and the mean interferon production was significantly depressed in the patients in remission. The mean transformation and interferon production in response to herpes simplex virus (HSV) among 34 HS seropositive patients did not differ from that among 51 normal HSV seropositive subjects; similar results were found among HSV seropositive patients in remission. There was no correlation between defective responses to VZV antigen and pathological diagnosis or stage in the untreated group, nor were the responses correlated with splenectomy or mode of treatment in the remission group. Marked suppression of interferon production and an even greater suppression of lymphocyte transformation were observed in 28 patients tested during the first 6 mo of therapy. The data suggest that lymphocyte transformation by VZV antigen appears to be restored with successful treatment of lymphoma in most patients, whereas the capacity to produce interferon in normal titers remains suppressed in some patients for a prolonged period of time. (28 refs)

- 79-5160 DNA of Epstein-Barr Virus. V. Direct Repeats of the Ends of Epstein-Barr Virus DNA. (Eng) Given, D. (Section Infectious Disease, Dept. Medicine, Univ. Chicago, Kovler Viral Oncology Labs., Chicago, IL 60637); Yee, D.; Griem, K.; Kieff, E. *J Virol* 30(3): 852-862; 1979.

To determine whether the terminal DNA of Epstein-Barr virus (EBV) is a direct or inverted repeat, the structures

formed after denaturation and reannealing of the DNA from one terminus and after annealing of lambda exonuclease-treated DNA were examined electron microscopically. (1) No inverted repeats were detected within the *SalI* D or *EcoRI* D terminal fragments of EBV DNA. The absence of "hairpin- or panhandlelike" structures in denatured and partially reannealed preparations of the *SalI* D or *EcoRI* D fragment and the absence of repetitive hairpin- or panhandlelike structures in the free 5' tails of DNA treated with lambda exonuclease indicated that there is no inverted repeat within the 3×10^5 -dalton terminal reiteration. (2) Denatured *SalI* D or *EcoRI* D fragments reannealed to form circles ranging in size from 3×10^5 to 2.5×10^6 daltons, indicating the presence of multiple direct repeats within this terminus. (3) Lambda exonuclease treatment of the DNA extracted from virus that had accumulated in the extracellular fluid resulted in asynchronous digestion of ends and extensive internal digestion, probably a consequence of nicks and gaps in the DNA. Most full-length molecules, after 5 min of lambda exonuclease digestion, annealed to form circles, indicating that there exists a direct repeat at both ends of the DNA. (4) The findings of several circularized molecules with small, largely double-stranded circles at the juncture of the ends indicated that the direct repeat at both ends is directly repeated within each end. Hybridization between the direct repeats at the termini is likely to be the mechanism by which EBV DNA circularizes within infected cells. (28 refs)

- 79-5161 Analysis of the Transformation of Human Lymphocytes by Epstein-Barr Virus. I. Sequential Occurrence from the Virus-determined Nuclear Antigen Synthesis, to Blastogenesis, to DNA Synthesis. (Eng) Takada, K. (Dept. Virology, Cancer Inst., Hokkaido Univ. Sch. Medicine, Sapporo, Japan); Osato, T. *Intervirology* 11(1): 30-39; 1979.

A B-cell population of human cord blood lymphocytes was exposed to the B95-8 strain of Epstein-Barr virus (EBV), and simultaneous observations of immunofluorescence, cellular morphology and autoradiography were carried out in each individual cell. It was evident that EBV-determined nuclear antigen (EBNA) synthesis occurred prior to blastogenic response and DNA synthesis. EBNA-positive cells could be observed as early as 12 hr after infection and reached a maximum of 17% at 24 hr, followed by a plateau for a subsequent 12 hr. The positive cells were seen exclusively as morphologically normal lymphocytes until 18 hr; at 24 hr, blastogenesis became evident, without cell division. DNA synthesis was detected at 36 hr in EBNA-positive blast cells; subsequently, these cells increased rapidly. EBNA synthesis was similarly evident in the presence of cytosine arabinoside (10 or 20 $\mu\text{g/ml}$) but was significantly inhibited by a short-term exposure to cycloheximide (10 or 20 $\mu\text{g/ml}$) immediately after infection. These findings suggest that the early events in EBV-induced transformation of human lymphocytes occur sequentially from EBNA synthesis, to blastogenesis, to DNA

synthesis and that the crucial step in such transformation probably involves protein synthesis occurring in the very early stage of EBV infection. (14 refs)

- 79-5162 Recovery of Epstein-Barr Virus from Non-producer Neonatal Human Lymphoid Cell Transformants. (Eng) Wilson, G. (Dept. Pediatrics, Howard Hughes Medical Inst. Lab., Yale Univ. Sch. Medicine, New Haven, CT 06510); Miller, G. *Virology* 95(2): 351-358; 1979.

Biological evidence concerning the complexity of Epstein-Barr virus (EBV) DNA in nonproducer cells transformed in vitro is presented. Lymphoid cell lines (LCL) were established by infection of two batches of human umbilical cord lymphocytes with low multiplicities of the B95-8 strain of EBV. Three of the 17 lines released minute amounts of transforming virus; the rest did not, and they did not make capsid antigen. However, virus could be regularly recovered by lethal x-irradiation of transformed cells followed by cocultivation of these cells with primary human umbilical cord WBC. By this technique, transforming activity could be identified in 15/17 lines. These data indicate that the nonproducer human neonatal cell transformants established by EBV infection in vitro possess sufficient genetic information to code for the production of biologically active mature virions. X-rays alone failed to cause a detectable increase in the number of cells with capsid antigen or to enhance extracellular virus production. EBV-positive human serum blocked rescue if it was added during the first 2-4 hr after cocultivation, but not thereafter. Transforming virus could be recovered from x-rayed cells that were then immediately lysed by freezing and thawing. These results suggest that recovery of virus following x-ray and cocultivation is not due to activation of the intracellular virus genome. Rather, it is likely that the method detects small numbers of virions that are cell-associated. Although transforming virus could regularly be rescued from lymphoblastoid cell lines resulting from in vitro transformation, attempts to rescue virus from Raji or EBV-converted BJAB cells were unsuccessful. This discrepancy suggests that there are differences in genome complexity or in genome-cell interactions in different types of EBV-transformed cells. (19 refs)

- 79-5163 Antibody-dependent Autologous Lymphocyte Cytotoxicity Against Cells Freshly Transformed by Epstein-Barr Virus. (Eng) Aya, T. (Dept. Virology, Cancer Inst., Hokkaido Univ. Sch. Medicine, Sapporo, Japan); Matsuo, T.; Takada, K.; Osato, T.; Mizuno, F. *IARC Sci Publ* 24(11): 711-719; 1978.

Cytotoxicity against lymphocytes freshly transformed by Epstein-Barr virus (EBV) was studied in an autologous

system by trypan blue exclusion of EBV nuclear antigen (EBNA)-cells and by the ^{51}Cr -release assay. When EBV-transformed lymphocytes were incubated with EBV-positive serum and autologous unfractionated lymphocytes or K-cells from seropositive healthy donors, the transformed cells were significantly damaged. The cytotoxicity against newly produced EBNA-positive lymphocytes was also remarkable when seropositive healthy donor lymphocytes were exposed to EBV, immediately followed by incubation with positive serum. In contrast, EBV-transformed cells incubated with autologous lymphocytes or T-cells alone were not significantly affected. EBV-positive serum alone was also not cytotoxic, regardless of inactivation. These results strongly suggest that antibody-dependent cellular cytotoxicity (ADCC) plays an important role in immunological defense against EBV oncogenesis in healthy humans. However, ADCC was not seen when immunosuppressed patients were examined. (12 refs)

- 79-5164 Surface Glycoprotein Patterns of Human Haematopoietic Cell Lines. (Eng) Gahmberg, C. G. (Univ. Helsinki, Helsinki, Finland); Anderson, L. C.; Nilsson, K. *IARC Sci Publ* 24(11): 649-653; 1978.

A surface-labeling technique was used to obtain the surface glycoprotein (gp) profile of human hematopoietic cell lines. The exposed surface gp's were labeled with tritiated sodium borohydride after treatment with neuraminidase and galactose oxidase. The radioactive gp's were separated on polyacrylamide slab gels and visualized by autoradiography. Epstein-Barr virus-positive and -negative lines were shown to have different and easily distinguishable surface gp patterns. (7 refs)

- 79-5165 EBV-associated Immune Complexes and Recurrent Burkitt's Lymphoma. (Eng) Gunven, P. (Dept. Tumor Biology, Karolinska Institutet, Stockholm, Sweden); Klein, G.; Rosen, A.; Mukojima, T. *IARC Sci Publ* 24(11): 875-882; 1978.

Epstein-Barr virus (EBV)-associated immune complexes were studied in four patients with Burkitt's lymphoma recurring after at least 6-mo remission. Three of these patients had a sudden decrease in anti-EBV-associated cell-membrane antigen (MA) prior to relapse. Low pH filtration of the patients' sera significantly increased anti-MA reactivity above that of serum or control IgG from the periods preceeding the fall in titer. When correction for Ig-G concentration differences was possible, this increased the titer differences. In contrast, the relatively highly reactive sera and their derived fractions generally did not differ markedly in anti-MA reactivity. One exception was probably due to an artefact. In another case, the latest serum from a patient showed a higher anti-MA titer in the low pH-filtered sample than in its control, which suggested that

the factor(s) responsible for the increase in titer after filtration of the low-reactive sera were also present in this serum. Findings indicating the presence of immune complexes with MA specificity in prerecurrence sera in BL suggest that the complexes may promote tumor recurrence, rather than being a consequence of tumor growth. - 79-5166 IgA and Nasopharyngeal Carcinoma. (Eng) Desgranges, C. (International Agency Res. Cancer, Lyon, France); de-The, G. *IARC Sci Publ* 24(II): 883-891; 1978.

Comparison of sera from patients with nasopharyngeal carcinoma (NPC) with those from patients with Burkitt's lymphoma (BL) or cancers of the head and neck showed that anti-Epstein-Barr virus (EBV) early antigen IgA titers were positive (>5) in the NPC patients only, and that anti-EBV viral capsid antigen IgA titers were higher than 1/40 in the NPC patients and much lower in the other patients. Transforming EBV was found in 9% of NPC salivas, 50% of BL salivas, and 67% of infectious mononucleosis salivas, although the nontransforming salivas did contain EBV clusters. IgA was found only in NPC salivas. These secretory IgA could be used as a rapid means of diagnosing NPC. IgA chains (α) were found in the plasmocytes surrounding NPC tumor tissue, whereas the secretory pieces were present in gland cells as well as in the epithelial tumor cells. (9 refs)

- 79-5167 Evaluation of Delayed Hypersensitivity Reactions to Lymphoid Cell Lines and Antibodies to Epstein-Barr Virus. (Eng) Levine, P. H. (NCI, NIH, Bethesda, MD 20014); Ho, J. H.; Nkrumah, F.; Andrese, A. P. *IARC Sci Publ* 24(II): 893-898; 1978.

Delayed hypersensitivity reactions to the nasopharyngeal carcinoma (NPC)-derived lymphoid cell line HKLY-28 and antibodies (ab) to Epstein-Barr virus (EBV) were measured in 60 Chinese patients with NPC, 20 patients with other carcinomas, and 27 patients with Burkitt's lymphoma. The 20 NPC patients who were positive by skin test to HKLY-28 showed higher Ab titers to EBV nuclear antigen ($p < 0.001$) and lower ab titers to EBV early antigen ($P < 0.001$) than the 40 patients who were skin test-negative to HKLY-28. There were no significant differences in ab titers to EBV viral capsid antigen or in ab-dependent lymphocyte cytotoxicity. Among the BL patients there were no significant differences among those who showed negative or positive skin test responses to Raji cell line HMP. (13 refs)

- 79-5168 Inhibition by Phosphonoacetate of the In Vitro Outgrowth of Epstein-Barr Virus

Genome-containing Cell Lines from the Blood of Infectious Mononucleosis Patients. (Eng) Rickinson, A. B. (Dept. Pathology, Univ. Bristol Medical Sch., Bristol, England); Finerty, S.; Epstein, M. A. *IARC Sci Publ* 24(II): 721-728; 1978.

Experiments were undertaken to determine the extent to which Epstein-Barr virus (EBV) genome-containing cell lines in cultures of WBC from infectious mononucleosis (IM) patients arise through the direct in vitro outgrowth of cells transformed in vivo by the virus or, alternatively, through the transforming action of virus particles released into the culture medium by cells nonproductively infected in vivo. IM leukocytes were cultured under conditions specifically inhibitory to full virus replication. Phosphonoacetate (PA), added to the culture medium at 50 $\mu\text{g}/\text{ml}$, reduced EBV replication in producer cell lines to 1% of the control values, but it did not significantly affect the colony-forming ability of EBV-transformed cell lines or the efficiency of transformation of lymphocytes infected in vitro. When mononuclear cell preparations from IM blood were depleted of T cells and then cultured in the presence of 50 $\mu\text{g}/\text{ml}$ PA, the appearance of cell lines was almost totally inhibited; the occasional EBV genome-containing cell lines that appeared in PA-treated cultures after a long delay were composed of cells indistinguishable in terms of growth rate and morphology from cells arising in corresponding control cultures. In further experiments in which IM cells were cocultivated with fetal cells of opposite sex, the few cell lines that arose in PA-treated cultures were of mixed or of fetal origin, suggesting that they had arisen via the much reduced two-step mechanism and not through the direct outgrowth of IM cells already transformed by the virus in vivo. These results suggest that EBV nuclear antigen expression in circulating IM cells probably denotes the early stages of an infectious cycle rather than cellular transformation. (18 refs)

- 79-5169 Replication of Epstein-Barr Virus DNA in Epithelial Cells In Vivo. (Eng) Lemon, S. M. (Div. Infectious Disease, Dept. Medicine, Univ. North Carolina, Chapel Hill, NC); Hutt, L. M.; Shaw, J. E.; Li, J. L.; Pagano, J. S. *IARC Sci Publ* 24(II): 739-744; 1978.

Epstein-Barr virus (EBV)-specific complementary RNA (cRNA) was hybridized in situ to oropharyngeal epithelial cells taken from patients with infectious mononucleosis. Cells from patients shedding virus in the throat hybridized significant quantities of cRNA, whereas cells from EBV-negative sources did not. The degree of hybridization indicated a large EBV genome number per infected epithelial cell and suggested that these cells were the source of virus found in the throat. This finding may explain the presence of the EBV genome in the malignant epithelial cells of nasopharyngeal carcinoma patients. (12 refs)

79-5170 Cellular Immunity in Infectious Mononucleosis: I. Spontaneous and Phytohaemagglutinin-induced Blast Transformation in Infectious Mononucleosis, with Special Reference to Depressed Cellular Reactivity and Stimulation-blocking Serum Factors. (Eng) Nikoskelainen, (Dept. Medicine, Univ. Turku, Turku, Finland); Stevens, D. A.; Neel, E. U.; Isenberg, R. A.; Miller, R. G.; Halpern, J. W.; Gelpi, A. P. *IARC Sci Publ* 24(II): 699-709; 1978.

Lymphocytes of patients with infectious mononucleosis (IM), Epstein-Barr virus (EBV) seropositive subjects, patients with viral infections other than EBV, and EBV seronegative subjects were tested for phytohemagglutinin (PHA)-induced and spontaneous transformation in vitro. Lymphocytes of EBV seropositive healthy subjects, tested in autologous serum, had higher spontaneous transformation than those of EBV sero-negative subjects. IM patients, in the acute phase of illness, had depressed spontaneous lymphocyte transformation, independent of serum factors. Serum factors were present in acute IM that depressed spontaneous transformation further, and to a lesser extent depressed reactivity to PHA. By the time the IM patients had recovered (>9 weeks after onset of illness), the observed defects had disappeared. (15 refs)

79-5171 Detection of Epstein-Barr Virus-coded Antigens in Lymphocytes Isolated From Defined Patient Samples. (Eng) Veltri, R. W. (Dept. Surgery Microbiology, West Virginia Univ. Medical Center, Morgantown, WV); McClung, J. E.; Sprinkle, P. M. *IARC Sci Publ* 24(II): 729-732; 1978.

A preliminary report on the use of specific rabbit antisera raised to the Epstein-Barr virus (EBV) nuclear antigen (EBNA) and early antigen (EA) for detection of these antigens in vivo is presented. Human lymphocytes were isolated on isokinetic gradients; and the C3 receptor-bearing B-lymphocyte subpopulation was isolated, providing an enriched source of EBV-infected lymphocytes. Such technology was employed to establish the status of the EBV host-cell complex in recurrent exudative tonsillitis (RET), infectious mononucleosis (IM), and Hodgkin's and non-Hodgkin's lymphoma patients. Only EBNA was detected in the lymphocytes from the tonsils of RET patients and the peripheral blood of IM patients. However, the spleen and lymph nodes of lymphoma patients had lymphocytes synthesizing EBNA and EA. (12 refs)

79-5172 Twenty-One Years of Follow-up Studies of Familial Epidermodysplasia Verruciformis. (Eng) Jablonska, S. (Dept. Dermatology, Warsaw Sch. Medicine, Koszykowa 82a, 02-008 Warsaw, Poland); Orth, G.; Jarzabek-Chorzelska, M.; Glinski, W.; Obalek, S.; Rzeska, G.; Croissant, O.; Favre, M. *Dermatologica* 158(5): 309-327; 1979.

A 21-yr follow-up study of a family with epidermodysplasia verruciformis (EV) showed that members of one family can be infected with different human papillomaviruses (HPV's), either HPV-3 or HPV-4, or, sometimes, with both. Three generations of the family were affected. The clinical picture was that of disseminated flat warts in cases induced by HPV-3, whereas in those caused by HPV-4 there were flat red or red-brownish plaques and unpigmented pityriasis lesions. Malignancies developed only in family members infected with HPV-4, whereas the cases due to HPV-3 ran a more benign and slowly progressive or stationary course. There were also abortive and regressive cases, and the three children in whom the wartlike lesions did not recur after removal had an unimpaired cell-mediated immunity (CMI). In all cases of EV, irrespective of the inducing virus, CMI was low, a factor that seems to be important in the pathogenesis of the disease. Humoral antibodies directed specifically against HPV-3 were present in most of the cases, mainly in those infected with HPV-3. (37 refs)

79-5173 Role of Interferon in the Pathogenesis of Herpes Simplex Virus Disease in Mice. (Eng) Gresser, I. (Institut de Recherches Scientifiques sur le Cancer, Villejuif, France); Tovey, M. G.; Maury, C.; Bandu, M. T. *IARC Sci Publ* 24(II): 1049-1054; 1978.

The role of interferon in the pathogenesis of herpes simplex virus (HSV) disease was studied in pathogen-free Swiss and C3H mice. Iv administration of a sheep antimouse interferon globulin resulted in the early appearance of disease and death, and it increased the overall mortality due to HSV type 1 injected ip or sc. The enhancing effect was most striking when HSV was inoculated sc. Twenty-five mice that had survived HSV inoculation were injected iv with antiinterferon globulin 18 days after virus inoculation. In no instance did this treatment induce signs of HSV disease. These results demonstrate the importance of the early interferon response in the pathogenesis of HSV disease in mice. (7 refs)

79-5174 Replication of Herpes Simplex Virus in Human B Lymphocytes Stimulated by Epstein-Barr Virus. (Eng) Kirchner, H. (Institut fur Virusforschung, Deutsches Krebsforschungszentrum, Im Neuenheimer Feld 280, D-6900 Heidelberg 1, W. Germany); Schroder, C. H. *Intervirology* 11(1): 61-65; 1979.

The replication of herpes simplex virus (HSV) in human B lymphocytes stimulated by Epstein-Barr virus (EBV) is reported. Human WBC were obtained from unselected adult blood (AB) and cord blood (CB) samples and processed by a Ficoll-Hypaque technique. T and B cells were separated with the use of neuraminidase-treated sheep

LIBRARY U. OF I. URBANA - CHAMPAIGN

RBC. Two populations were obtained: population B, containing <2% of T cells, and population T, containing <2% B cells. The B and T cells were stimulated with phytohemagglutinin (PHA), pokeweed mitogen (PWM), or two strains of EBV, B95-8 and P3HT-1. B95-8 induced high levels of ³H-thymidine incorporation in CB and AB cultures of B cells. It was unreactive in the T cells. P3HR-1 was unable to induce DNA synthesis in either B or T lymphocytes. P3HR-1 suppressed DNA synthesis in B lymphocytes stimulated by B95-7. PWM or PHA did not stimulate purified B lymphocytes. When AB or CB B cells were preincubated for various periods of time in the presence of B95-8 and then infected with HSV, marked replication of HSV could be demonstrated. There was no HSV replication in B cells pretreated with P3HR-1 or in T cells pretreated by either EBV strain. However, after T cells were prestimulated with PWM, they were able to replicate HSV. Thus, both T and B cells can replicate HSV provided they are preactivated with the appropriate mitogen. Enriched monocyte populations (60%-70% monocytes, obtained after 2 cycles of plastic adherence) were unable to replicate HSV regardless of which mitogen was used. (16 refs)

79-5175 Virological and Serological Studies in Pregnancy, in Women with Suspect Genital Herpes Simplex Virus or Perinatal Cytomegalovirus Infections, and in Women with Carcinoma of the Cervix. (Eng) Frenkel, L. D. (Medical Coll. Ohio at Toledo, Toledo, OH); Crawford, M. A.; Bellanti, J. A. *IARC Sci Publ* 24(11): 911-915; 1978.

To assess the concomitant virological and serological markers of genital herpes simplex virus (HSV) and perinatal cytomegalovirus (CMV) infection, 25 pregnant women, 52 women with a history of recurrent HSV infection, 22 women with suspected CMV infection, 11 women with carcinoma of the cervix in situ (CIS), and 47 matched controls were studied. Urine and cervical viral cultures from normal controls and women with CIS yielded no HSV or CMV. HSV was isolated from three pregnant women and CMV was isolated from two pregnant women. CMV was isolated from six nonpregnant women, and HSV was isolated from 16 nonpregnant women, 2 of whom were also intermittently positive for CMV. Geometric mean titers (GMT) to CMV and HSV were slightly elevated in the pregnant subjects, and the percentage of seronegative pregnant women was considerably smaller than that of controls. GMT to CMV were significantly higher in women with suspected CMV and to HSV-1 and HSV-2 in women who had a history of recurrent herpes genitalis. GMT to all three viruses were elevated in women with CIS ($p < 0.005$), and none of them were seronegative. (10 refs)

79-5176 Poly(adenosine Diphosphate Ribose) Synthesis During Herpes Simplex Virus Infection.

(Eng) Muller, W. E. (Institut für Physiologische Chemie, Abteilung Angewandte Molekularbiologie, Duesbergweg, D-6500 Mainz, W. Germany); Falke, D.; Zahn, R. K.; Arendes, J. *Intervirology* 11(3): 182-187; 1979.

The effect of poly(adenosine diphosphate ribose) [poly(ADP-Rib)] synthesis on the synthesis of DNA in herpes simplex virus (HSV)-infected baby hamster kidney (BHK-21) cells was determined. Cellular DNA synthesis was blocked immediately after infection. After almost complete inhibition of host cell DNA formation at 3.5 hr postinfection, extensive HSV DNA synthesis began. These dramatic alterations of the control mechanisms for the two DNA-synthesizing systems were not accompanied by a significant change in poly(ADP-Rib) polymerase activity. Thus, during the suppression of cellular DNA synthesis and the onset of viral DNA synthesis, chromatin-bound and extractable poly(ADP-Rib) polymerase activity remained unaltered. Poly(ADP-Rib) may represent a structural element in the organization of chromatin and it may have some biological function in chromosome condensation during mitosis. (30 refs)

79-5177 Isolation and Localization of Herpes Simplex Virus Type 1 mRNA. (Eng) Anderson, K. P. (Dept. Molecular Biology and Biochemistry, Univ. California at Irvine, Irvine, CA 92717); Stringer, J. R.; Holland, L. E.; Wagner, E. K. *J Virol* 30(3): 805-820; 1979.

Two independent methods were used to determine the size ranges of specific herpes simplex virus type 1 (HSV-1) messenger RNA (mRNA) species synthesized late after infection and to localize individual transcripts to specific regions of the viral genome. Restriction fragments of HSV-1 DNA bound to cellulose were used to isolate viral mRNA for size analysis on denaturing agarose gels. Total viral polysomal polyadenylated RNA was isolated from cells late after infection, when this RNA has sequences encoded by approx 45% of the HSV DNA. This RNA has a size range of from 1.5 to ≥ 8 kilobases (kb), with certain sizes, such as 1.7 to 1.9 kb, being favored. The restriction endonucleases *Hind*III and *Xba*I were used singly and together to generate various-sized fragments covering the entire HSV-1 genome. These fragments were bound to cellulose to allow isolation of HSV-1 mRNA annealing to different regions of the viral genome. Discrete sizes of viral mRNA were associated with certain regions of the genome, but the mRNA population hybridizing to even the smallest restriction fragments was complex. Hybridization of size-fractionated RNA to Southern blots of restriction fragments of HSV-1 DNA generated by the *Bgl*II as well as *Hind*III and *Xba*I endonucleases was used to confirm the preparative hybridization data and to provide some overlap data for positioning transcripts. The data of blot and preparative hybridization agreed very well, and they were combined to construct a preliminary transcription map of HSV-1. This map revealed at least two areas of the long unique region of the HSV-1

genome that annealed to a large number of HSV-1 transcripts. Furthermore, discrete-sized mRNA species >5 kb long were found only in the middle of the long unique region. (39 refs)

- 79-5178 Alterations in the Protein Synthetic Apparatus of Cells Infected with Herpes Simplex Virus. (Eng) Silverstein, S. (Dept. Microbiology, Coll. Physicians and Surgeons, Columbia Univ., 701 W. 168th St., New York, NY 10032); Engelhardt, D. L. *Virology* 95(2): 334-342; 1979.

The effect of herpes simplex virus (HSV) infection on the rate of protein synthesis, the distribution of ribosomes, and the time required to complete nascent peptides (transit time) was examined in actively growing or stationary phase Vero cells. The rate of protein synthesis per polysomal ribosome decreased continuously throughout the early portion of the infection cycle. This occurred despite an increase in the accumulation of ribosomes in polysomelike structures that accompanies the onset of synthesis of HSV-specified proteins. Transit-time measurements demonstrated that the rate of polypeptide elongation was not altered after infection. These data are discussed in light of a model that suggests that polysomelike structures are present but not functioning (or functioning very poorly) in HSV-infected cells. (24 refs)

- 79-5179 Location of Non-Temperature-sensitive Genes on the Genetic Map of Herpes Simplex Virus Type 1. (Eng) Brown, S. M. (Medical Res. Council Virology Unit, Inst. Virology, Glasgow, Scotland); Jamieson, A. T. *IARC Sci Publ* 24(1): 33-39; 1978.

By constructing three-factor crosses involving the genes coding for deoxypyrimidine kinase and for resistance to the drug phosphonoacetic acid, it was possible to extend the genetic analysis of herpes simplex virus type 1 such that the eight possible progeny genotypes that arise from these crosses could be identified and to precisely locate the gene for the plaque-morphology marker (*sym*), the gene for deoxypyrimidine kinase (*dPyK*), and the gene for resistance to phosphonoacetic acid (*PAAr*). (3 refs)

- 79-5180 Characterization of Pyrimidine Deoxyribonucleoside Kinase (Thymidine Kinase) and Thymidylate Kinase as a Multifunctional Enzyme in Cells Transformed by Herpes Simplex Virus Type 1 and in Cells Infected with Mutant Strains of Herpes Simplex Virus. (Eng) Chen, M. S. (Dept. Pharmacology, Yale Univ. Sch. Medicine, New Haven, CT 06510); Summers, W. P.; Walker, J.; Summers, W. C.; Prusoff, W. H. *J Virol* 30(3): 942-945; 1979.

Thymidylate kinase activity was studied in cells infected with herpes simplex virus type 1 (HSV-1) with mutations in the pyrimidine deoxyribonucleoside kinase [thymidine kinase (TK)] gene as well as in cells stably transformed to the TK⁺ phenotype. TK was purified from two HSV-1-transformed TK-deficient mouse (LMTK⁻) cell lines and from LMTK⁻ cells infected with HSV-1 mutant viruses coding for variant TK enzymes. These preparations exhibited normal or variant virus-induced thymidylate kinase activities correlating with their relative TK activities. Neither virus-induced activity was detected in LMTK⁻ cells infected with an HSV-1 TK-deficient mutant. These results suggest that a single HSV-1 gene codes for a multifunctional enzyme with thymidylate kinase activity and TK activity. (14 refs)

- 79-5181 Sequential Changes in Cell-mediated Immune Responses to Herpes Simplex Virus Following Primary Herpetic Infection in Man. (Eng) Shillitoe, E. J. (Dept. Oral Medicine and Hosp. Dentistry, Univ. California, Sch. Dentistry, San Francisco, CA); Wilton, J. M.; Lehner, T. *IARC Sci Publ* 24(11): 753-758; 1978.

Sequential changes in cell-mediated immune responses to herpes simplex virus type 1 (HSV-1) were studied in 5 patients with primary herpetic stomatitis, 2 patients with primary herpetic infection of the hand, and 19 normal controls. HSV-1 antibodies, which were detectable in only 2/6 patients at presentation, were detected in the sera of all patients 14-21 days after the onset of symptoms. The lymphocyte stimulation index in response to HSV-1 was significantly greater in patients who had symptoms for up to 7 days than in seropositive controls ($P < 0.02$). The response declined but was still greater than that of seronegative controls after 21 days ($P < 0.01$). Responses to purified protein derivative of tuberculin (PPD) and phytohemagglutinin were similar in patients and controls at presentation and 14 days later. Mean migration indices of supernatants of HSV- and of PPD-stimulated lymphocytes were similar among seronegative and seropositive controls and patients. However, macrophage migration inhibition increased between the first and last test performed on each patient ($P < 0.02$). The data suggest that recovery from herpetic infection coincides with the appearance of antibody and of macrophage migration inhibition and not with lymphocyte sensitization. (7 refs)

- 79-5182 Immunological Nature of Genetic Resistance of Mice to Herpes Simplex Virus Type 1 Infection. (Eng) Lopez, C. (Sloan-Kettering Inst. Cancer Res., New York, NY). *IARC Sci Publ* 24(11): 775-781; 1978.

Adult C57Bl/6 and A/J mice were studied to determine whether genetic resistance to herpes simplex virus type 1

(HSV-1) is immunologically mediated. The importance of T cells and macrophages in genetic resistance to HSV-1 was demonstrated. Lethally irradiated A/J mice (highly susceptible) given bone marrow transplants from resistant (C57Bl/6 x A/J)F₁ mice were more resistant to HSV-1 challenge than were untreated A/J mice. The in vitro capacity of isolated macrophages to restrict HSV-1 replication did not reflect in vivo resistance. There was a striking similarity between the capacity of mice to resist HSV-1 infections and their ability to resist allogeneic marrow grafts. The only major difference was that allogeneic resistance was more radioresistant than was resistance to HSV-1. (21 refs)

79-5183 The Alterations of PK and LDH Activities in the Cells Infected with Herpes Virus; The Effects of Anti-PK IgG and Anti-Herpes Serum on These Alterations. (Eng) Moldoveanu, N. (Inst. Biological Sciences, Splaiul Independenței 296, Bucharest, 77748 Romania); Tanasescu, D.; Nachtigal, M. *Rev Roum Biochim* 15(4): 305-309; 1978.

Pyruvate kinase (PK), lactate dehydrogenase (LDH), and protein levels were determined in cultures of HEp-2 cells infected with herpes simplex virus type 1 VR (prepared on rabbit kidney cell cultures) in the presence or absence of rabbit antiherpes serum or anti-PK IgG (obtained from chickens inoculated with purified bovine muscle PK). The protein content of virus-infected HEp-2 cells was similar to that of control cells during the first 12 hr, but it was significantly lower at 48 hr after inoculation. LDH and PK activities increased at 24 hr, but they showed significant decreases at 48 hr postinfection. The antiherpes serum and anti-PK IgG exhibited a protective effect against the virus-induced inhibition of protein and enzymes. (17 refs)

79-5184 Apparent Absence of Virus-specific Transplantation Rejection Antigen in Herpes Simplex Virus-transformed Hamster Cells. (Eng) Lausch, R. N. (Dept. Microbiology and Immunology, Coll. Medicine, Mobile, AL); Hay, K. A. *IARC Sci Publ* 24(II): 905-910; 1978.

The 14-012-8-1, T-10 cell line was used to determine whether cells transformed by herpes simplex virus type 1 (HSV-1) express transplantation rejection antigen and whether HSV-1 immunization influences the incidence of tumor metastases. Hamsters sensitized to the tumor cells by intradermal inoculations of 10⁵ cells, followed 10-15 days later, by excision of the tumor were resistant to low challenge doses of a subsequent isograft, as evidenced by reduced tumor incidence and increased latent period. Thus, the cells did express transplantation rejection antigen. However, immunization of hamsters with three inoculations of HSV-1 provided no significant protection against

challenge with low doses of 14-012-8-1, T-10 cells. Therefore, the transplantation antigen detected in the concomitant immunity experiments was not virus associated. Immunization with HSV-1 or HSV-2 did not appear to enhance or inhibit the incidence of tumor metastases in comparison with normal or cytomegalovirus-sensitized controls. (8 refs)

79-5185 Reduction of ⁵¹Cr-Permeability of Tissue Culture Cells by Infection with Herpes Simplex Virus Type 1. (Eng) Schlehofer, J. R. (Institut für Klinische und Experimentelle Virologie der WE04, Freie Universität Berlin, Hindenburgdamm 27, D-1000 Berlin 45, W. Germany); Habermehl, K. O.; Diefenthal, W.; Hampl, H. *Intervirology* 11(3): 158-166; 1979.

The protection of herpes simplex virus type 1 (HSV-1)-infected cells from immunological injury and from several cytotoxic agents was demonstrated. The infection of HEp-2, Chang liver, FL, baby hamster kidney (BHK-21), rabbit kidney, HeLa, and KB cells with HSV led to a significant reduction of ⁵¹Cr release (CR). This effect began 6-8 hr postinfection. In chick embryo fibroblasts (CEF), however, HSV infection enhanced CR. The HSV-induced reduction of CR indicated that the permeability of the cellular membrane was altered. This assumption was confirmed by the finding of reduced incorporation of ⁵¹Cr into infected cells. The effect began 8 hr postinfection and correlated with the onset of the reduction in CR and with the logarithmic increase in HSV replication. CR was not due to a loss of ⁵¹Cr during HSV penetration or other events early in infection. With the exception of CEF, HSV increased the stability of the cells toward Triton X-100. In addition, HSV-infected HEp-2 cells were resistant to toxic guinea pig serum and to HSV-specific complement-mediated immune cytolysis. The HSV-induced stability of cellular membranes may play a part in the maintenance of latent infection. (13 refs)

79-5186 Herpes Simplex Virus Latency in Patients With Multiple Sclerosis, Lymphoma and Normal Humans. (Eng) Warren, K. G. (Multiple Sclerosis Res. Center of the Wistar Inst., Univ. Pennsylvania, Philadelphia, PA); Devlin, M.; Gilden, D. H.; Wroblewska, Z.; Koprowski, H.; Brown, S. M.; Shubik-Sharpe, J. *IARC Sci Publ* 24(II): 765-768; 1978.

Herpes simplex virus (HSV) was isolated from the trigeminal ganglia (TG) of 12 cadavers (10 traumatic deaths, one lymphoma and one multiple sclerosis). The cadaver with multiple sclerosis showed large bilateral trigeminal nerve root entry zone areas of demyelination that may have been initiated by HSV. (5 refs)

- 79-5187 Herpes Virus Infection as a Cofactor in Carcinogenesis. Supernatants of Herpes Virus Type 1- and Type 2-infected Cell Cultures Contain a Cell Growth-stimulating Factor. (Eng) Reiss-Gutfreund, R. J. (Inst. Cancer Res., Univ. Vienna, Borschkegasse 8a, A-1090 Vienna, Austria); Dostal, V.; Wenzel, J. *Oncology* 36(2): 55-62; 1979.

Following lytic infection with herpes simplex virus (HSV) type 1 or 2, some cell cultures synthesize a mitogenic factor (DNASF) that is shed into the medium. Of six cell lines permissive to HSV infection tested, three (CV1, HF, MCA) produced DNASF. In addition, significantly higher (³H)-thymidine incorporation was obtained with indicator cells growing in supernatants of virus-infected cells (SupV+) than in the corresponding supernatants of sham-treated cells (SupV-). In some cases, the values obtained with SupV+ exceeded those obtained with cell controls, which demonstrates that DNASF is not simply a nutritional factor. The cell lines that did not produce DNASF were HeLa, Wistar, and, probably, REF; SupV+ frequently inhibited cell growth in these lines. DNASF was genetically nonspecific, and all indicator cells tested were stimulated by supernatants that contained the mitogen, including the nonpermissive DC-3F cells. The quantity of DNASF induced was directly proportional to the number of cells in the culture, and its production peaked when cell lysis was complete. It did not accumulate inside the cells. (23 refs)

- 79-5188 Physical Mapping of Herpes Simplex Virus-coded Functions and Polypeptides by Marker Rescue and Analysis of HSV-1/HSV-2 Intertypic Recombinants. (Eng) Wilkie, N. M. (Dept. Virology, Inst. Virology, Univ. Glasgow, Glasgow, Scotland); Stow, N. D.; Marsden, H. S.; Preston, V.; Cortini, R.; Timbury, M. C.; Subak-Sharpe, J. H. *IARC Sci Publ* 24(1): 11-31; 1978.

Several temperature-sensitive (*ts*) mutants and one pyrimidine deoxyribonucleoside kinase-deficient mutant of herpes simplex virus (HSV) were located on the physical map of the genome by marker rescue experiments and by analysis of the crossover points in intertypic recombinants between HSV types 1 and 2. The physical map was compared with the genetic map, and certain anomalies were identified. Analysis of infected-cell polypeptides specified by intertypic recombinants allowed tentative map coordinates to be assigned to the structural genes (or genes that cause posttranslational modification) for many of the polypeptides. Immediate-early, phosphorylated, glycosylated, and structural as well as nonstructural polypeptides were analyzed in this way. It was concluded that there is no restriction of any of these groups of polypeptides to either the long or the short regions of the genome. One of the recombinants, 2853, is at least partially "frozen" in one orientation of the long region. This orientation is also the one that exhibits a minimum number of crossovers in three other recombinants. (28 refs)

- 79-5189 The Use of Intertypic Recombinants for Analysis of Gene Organization in Herpes Simplex Virus. (Eng) Morse, L. S. (Marjorie B. Kovler Viral Oncology Lab., Univ. Chicago, Chicago, IL); Pereira, L.; Roizman, B.; Schaffer, P. A. *IARC Sci Publ* 24(1): 41-61; 1978.

Herpesvirus type 1 (HSV-1) x HSV type 2 (HSV-2) recombinant DNA's with heterogeneous L and S components or with heterogeneous inverted repeats were studied to map the location of templates specifying the polypeptides on the HSV genome. HSV-1 and HSV-2 genes appeared to be functionally equivalent and with few exceptions were arranged colinearly. Colinear DNA maps were established. At most, two arrangements of HSV DNA were capable of replication. α Polypeptides mapped at the termini of the L and S components. Although α infected-cell polypeptide (ICP) 27 mapped entirely within the reiterated region of the L component, the template for α ICP 4 appeared to lie only in part within the reiterated sequences of the S component. Cells infected with a recombinant containing both HSV-1 and HSV-2 sequences in the S component produced α ICP 4 of both HSV-1 and HSV-2. Templates specifying β and γ polypeptides mapped in the L component and appeared to be distributed randomly. The genes specifying thymidine kinase, resistance to phosphonoacetic acid, and syncytial plaque morphology mapped in the L component. The gene(s) specifying the inhibition of host protein synthesis mapped in the L component. (35 refs)

- 79-5190 Immunoelectrophoretic Identification and Purification of Herpes Simplex Virus Antigens Released from Infected Cells in Tissue Culture. (Eng) Norrild, B. (Dept. Pediatrics, Emory Univ. Sch. Medicine, 69 Butler St. SE, Atlanta, GA 30303); Vestergaard, B. F. *Intervirology* 11(2): 104-110; 1979.

Proteins released from herpes simplex virus type 1 (HSV-1)- and type 2 (HSV-2)-infected HEP-2 cells have been characterized by the crossed immunoelectrophoretic technique. Both HSV type-common and type-specific antigens were found in the tissue culture medium 24 hr after infection. Antigen Ag-6, an HSV-1-specific antigen, was found in high concentration in the medium as compared to other HSV antigens released from HSV-1-infected cells. The HSV-2-specific antigens, Ag-4 and Ag-1, were released in molecular modifications with altered electrophoretic mobility as compared to their cellular counterparts. Purification of HSV antigens was performed by ion-exchange chromatography, and an HSV type-common antigen, Ag-11, and an HSV-2-specific antigen, Ag-4A, were isolated. (13 refs)

- 79-5191 Presence of Antibody Against Herpes Simplex Virus-specified Thymidine Kinase and Deoxyribonuclease in Human Sera. (Eng) Cheng, Y. C. (Dept.

Experimental Therapeutics, Roswell Park Memorial Inst., Buffalo, NY); Hoffmann, P. J.; Kung, M. P. *IARC Sci Publ* 24(11): 899-904; 1978.

Human sera were tested for their ability to inhibit the activity of herpesvirus type 1 (HSV-1) specific thymidine kinase (TK) and DNase and HSV-2 specific TK and DNase. All subjects who had experienced periodic fever blisters had antibody (Ab) against at least one of the virus-specified enzymes. Of 30 normal subjects, 4 had no inhibitory activity against any of the enzymes, 13 had activity against TK but not DNase, 1 had activity against DNase, and 12 had Ab against TK and DNase. Of 34 subjects with untreated prostatic, lung, or gastrointestinal tumors, 6 had Ab against TK and 28 had Ab against TK and DNase. With the exception of one patient, the inhibition of viral TK and DNase was type-specific. Of 13 patients with untreated, chronic myelocytic leukemia or Hodgkin's disease, 8 had Ab against TK, 3 had Ab against TK and DNase, and 2 had no activity against either enzyme. There was no evidence of cross-immunogenicity between TK and DNase derived from the same virus-infected cells. (17 refs)

79-5192 Experimental Infection of Tupaia with Herpes Simplex Virus Types 1 and 2. (Eng) Munk, K. (Institut für Virusforschung, Deutsches Krebsforschungszentrum, Heidelberg, W. Germany); Schwaier, A.; Darai, G. *IARC Sci Publ* 24(11): 789-793; 1978.

The susceptibility of *Tupaia belangeri* to infection by herpes simplex virus types 1 and 2 (HSV-1 and HSV-2) was studied. HSV was highly pathogenic for juvenile (28- to 40-day old) tupaia, resulting in death after 2-14 days. Death occurred earlier after iv than after ip or sc inoculation of HSV. The liver tissue of the diseased animals showed histomorphological changes resembling those of acute herpetic hepatitis. The spleen showed hyperemia, atrophy and fibrosis of the red pulp, and distinct necrotic changes. In some animals, the brain tissue showed edema, hyperemia, and hemorrhaging in the meninges, infiltration of lymphocytes, isolated cysts, and encephalitis. Viremia was observed 24-48 hr before death. Iv inoculation of HSV-2 into adult tupaia resulted in increased serum titers of neutralizing antibody but no symptoms of acute infection. Infectious virus was isolated from the lumbosacral segment of the spinal cord and gasserian ganglia of animals that survived HSV infection. (14 refs)

79-5193 Detection of Herpes Simplex Virus Type 2 mRNA in Human Cervical Biopsies by In Situ Cytological Hybridization. (Eng) Jones, K. W. (Inst. Animal Genetics, Univ. Edinburgh, Edinburgh, Scotland); Fenoglio, C. M.; Shevchuk-Chaban, M.; Maitland, N. J.; McDougall, J. K. *IARC Sci Publ* 24(11): 917-925; 1978.

In situ cytological hybridization was used to detect herpes simplex virus type 2 (HSV-2) messenger RNA (mRNA) in human cervical biopsies. The primary advantages of this method are direct examination of individual cells in smears or sections and amplification of target sequences as mRNA, provided that any integrated viral DNA is transcribed. Once optimal conditions are established for any particular virus, the in situ method will provide an extremely valuable means of detecting viral nucleic acid sequences in tumors. Of 8 cervical biopsy specimens (carcinoma or dysplasia) 5 were positive for HSV-2. (15 refs)

79-5194 Immune Responses to Vaginal or Systemic Infection of Mice with Herpes Simplex Virus Type 2. (Eng) Morahan, P. S. (Dept. Microbiology, Medical Coll. Virginia, Virginia Commonwealth Univ., Richmond, VA); Breinig, M. C.; McGeorge, M. B. *IARC Sci Publ* 24(11): 759-763; 1978.

Relationships among cell-mediated immune (CMI) responses, neutralizing antibody, and macrophages in host resistance to vaginal or systemic infection with herpes simplex virus type 2 (HSV-2) were defined in BALB/c mice. The importance of T lymphocytes in resistance to either systemic or vaginal infection was demonstrated by the increased susceptibility of mice depleted of T lymphocytes. A role for nonspecific resistance against systemic, but not vaginal, infection was demonstrated by the increased susceptibility of mice depleted of macrophages. The temporal relationships among the serum antibody, delayed-type hypersensitivity, and splenic proliferative CMI responses were defined in individual animals. Vaginal infection was associated exclusively with relatively transient CMI responses that appeared during the acute infection. After systemic infection, CMI responses appeared during the acute infection and persisted for approx 5 wk; a humoral response appeared in surviving animals and persisted for at least 4 mo. The results suggest that CMI is the predominant host response to vaginal HSV-2 infection and that both CMI and macrophage-mediated antiviral activity may be involved in recovery from primary systemic infection with HSV-2. (12 refs)

79-5195 Growth of Type 2 Herpes Simplex Virus in Newborn and Adult Mononuclear Leukocytes. (Eng) Trofatter, K. F. (Dept. Pathology, Duke Univ. Medical Center, Box 3712, Durham, NC 27710); Daniels, C. A.; Williams, R. J.; Gall, S. A. *Intervirology* 11(2): 117-123; 1979.

Growth of type 2 herpes simplex virus (HSV) in newborn and adult human mononuclear leukocytes (MNL) was compared. Phytohemagglutinin stimulation of cultures for 3 days yielded comparable peak titers in newborn [$10^{5.3}$ plaque-forming units (PFU)] and adult ($10^{5.1}$ PFU) MNL.

Unexpectedly, 3-day cultures of unstimulated newborn MNL also substantially replicated HSV ($10^{4.7}$ PFU), whereas similarly treated unstimulated adult cells did not. Growth of HSV in freshly isolated human MNL was investigated. MNL from 4 mothers and 6 nonpregnant adults showed no evidence of virus growth; however, leukocytes from 11 of 24 newborns (46%) supported replication. Newborn MNL manifested an increased ability to replicate HSV within 1 day of culture, whereas comparable growth in adult MNL was not achieved until the 4th day of culture. The significance of the above observations as it relates to visceral dissemination of HSV in the neonate is discussed. (26 refs)

- 79-5196 Stimulation of Chemical Carcinogenesis in Mice Chronically Infected with Herpes Simplex Virus Type 2. (Rus) Kitsak, V. Ia. (Central Inst. Advanced Training Physicians, Moscow, USSR); Moisiadi, S. A.; Bocharov, A. F. *Vopr Virusol* (3): 277-282; 1979.

The role of herpes simplex virus type 2 (HSV-2) in the etiology of chemically induced tumors was evaluated. Albino mice were inoculated sc with 20-methylcholanthrene (20-MC: 0.1 mg) and/or HSV-2 (at 70 times the LD_{50}). Tumors induced by 20-MC (alone or with HSV-2) were first recorded 74-81 days later; tumor incidence was max on days 94-122. 20-MC alone induced tumors in 29.5% of mice weighing 10-12 g (younger mice) and in 41.8% of mice weighing 25-30 g (older mice). HSV-2 alone had no carcinogenic activity. The combined administration of 20-MC and HSV-2 significantly increased the incidence of tumors (68.0% in younger mice and 66.6% in older mice). (26 refs)

- 79-5197 Classification of Human Adenoviruses by SDS-Polyacrylamide Gel Electrophoresis of Structural Polypeptides. (Eng) Wadell, G. (Dept. Virology, Karolinska Institutet, S-105 21 Stockholm, Sweden). *Intervirology* 11(1): 47-57; 1979.

Analysis of the polypeptide patterns of 15 human adenovirus serotypes by sodium dodecyl sulfate-polyacrylamide gel electrophoresis showed that capsid polypeptides 11, 111, 111a, and IV display a pattern of apparent mol wts that is characteristic for each adenovirus serotype analyzed. The results also suggested the feasibility of obtaining a subgroup classification based on the apparent mol wts of internal polypeptides V, VI, and VII and, to some extent, on the size of the hexon (polypeptide II) and the vertex capsomer (polypeptide III). (32 refs)

- 79-5198 High Molecular Weight Virus DNA in KB Cells Infected with *ts* Mutants of Adenovirus Type 2 under Permissive and Non-Permissive Conditions. (Eng) Schick, J. (Inst. Genetics, Univ. Cologne, Cologne, W. Germany); Doerfler, W. *J Gen Virol* 43(part 1): 217-222; 1979.

Temperature-sensitive mutants (*ts206* and *ts214*) of adenovirus type 2 (Ad2) which were deficient in virus DNA synthesis at the nonpermissive temperature were used to determine whether virus DNA replication is required for the occurrence of high mol wt Ad2 DNA (> 100S, 50-90S) in human KB cells productively infected with Ad2. Ad2-specified DNA sequences could be detected in all four size classes of newly synthesized DNA in cells infected with wild-type Ad2. After infection with *ts206* or *ts214*, the amount of 34S wild DNA synthesized at the nonpermissive temperature was reduced 15- to 34-fold compared to synthesis at the permissive temperature. The quantities of viral DNA sequences in the < 20S size class were reduced 16- to 22-fold at the nonpermissive temperature. The amount of viral DNA sequences in the high mol wt size classes were reduced only 3- to 4-fold at the nonpermissive temperature. These reductions tended to be even lower in the > 100S size class. Thus, unabated viral DNA replication is not a prerequisite for the integration event. Under conditions which allow the synthesis of a large number of virus genome copies, linkage of viral DNA sequences to cellular DNA might occur more frequently because of the larger pool of free viral DNA. (11 refs)

- 79-5199 Mosaic Adenovirus-SV40 RNA Specified by the Non-defective Hybrid Virus Ad2+ND₄. (Eng) Westphal, H. (Lab. Molecular Genetics, Natl. Inst. Child Health and Human Development, NIH, Bethesda, MD 20014); Lai, S. P.; Lawrence, C.; Hunter, T.; Walter, G. *J Mol Biol* 130(3): 337-351; 1979.

The structures of the simian virus 40 (SV40)-specific RNA's isolated from the cytoplasm of HeLa cells infected with the nondefective adenovirus 2-SV40 hybrid Ad2+ND₄ were determined by annealing the isolated RNA to Ad2, Ad2+ND₄, or SV40 DNA and examining the hybrids under an electron microscope. (The largest insert of SV40 DNA, comprising SV40 map positions 59 to 11, is found in Ad2+ND₄ DNA.) An attempt was made to establish in what way the structures of the SV40-specific RNA's allow the expression of proteins related to tumor antigen but not normally specified by SV40. A considerable proportion of the RNA was mosaic, consisting of Ad2 sequences at its 5' end and of SV40 RNA in the remainder of the molecule. The Ad2 sequences represented transcripts of separate segments of DNA. They started with the familiar tripartite leader of late Ad2 messenger RNA (mRNA), followed by various combinations of three separate sequences that are located between Ad2 map positions 75 and 79, preceding the SV40 insertion in Ad2+ND₄. The SV40

sequences within Ad2 + ND₄ RNA were often transcribed from noncontiguous segments as well. Some of these segments corresponded to those reported for RNA expressed by SV40 itself in early infection, others were quite different. The specific SV40 sequence arrangements in the mosaic RNA's allowed them to be correlated with individual translation products found in the infected cell. The intervening sequence common to SV40 and Ad2 + ND₄ was bounded by SV40 map positions 60 and 54. A deletion comprising this sequence was found in 80% of the Ad2 + ND₄ stocks. Sequences between 54 and 59 SV40 map units may be detrimental to the growth of Ad2 in human cells; ie, the presence of these sequences might interfere with the efficient processing of Ad2 transcripts into fiber mRNA, a gene that is downstream of the SV40 insertion. (33 refs)

- 79-5200 Human Brain Tumour Cell Strains with Deficient Host-Cell Reactivation of N-Methyl-N'-nitro-N-nitrosoguanidine-damaged Adenovirus 5.** (Eng) Day, R. S. (Nucleic Acids Section, Lab. Molecular Carcinogenesis, NCI, NIH, Bethesda, MD 20014); Ziolkowski, C. H. *Nature* 279(5716): 797-799; 1979.

To evaluate the hypothesis that human tumorigenesis is often associated with repair-deficient cells, the survival of adenovirus 5 (Ad5) treated in vitro with the carcinogen N-methyl-N'-nitro-N-nitrosoguanidine (MNNG) was studied in various types of human host cells. Ad5 was suspended in a soln of 0.5-2.0 mg/ml MNNG for 30 min at 37 C, viral inactivation was terminated with N-acetyl-L-cysteine, and plaque assays were performed. Cells from 4/13 brain tumor strains (A172, A382, U-87MG, and U-105MG, from a glioblastoma and 3 astrocytomas, respectively) resulted in less survival of MNNG-damaged viruses than did the cells of the remaining brain tumor strains and the cells of 20 strains prepared from other human tumors or unaffected human organs. Among host cell strains that showed normal reactivation of MNNG-damaged Ad5 were skin fibroblasts from patients with ataxia telangiectasia (3) and xeroderma pigmentosum (1); cells from patients with brain (9), kidney (3), and liver (1) tumors and with leukemia (2); and cells from three brain tumor-prone families. Strains A172, U-87MG, and U-105MG had normal host-cell reactivation of UV-irradiated viruses. The results were interpreted to mean that the A172, A382, U-87MG, and U-105MG cell strains are defective in their ability to repair MNNG-damaged Ad5. It is suggested that the repairable lesion may be a DNA-N-nitrocyanamide reaction product. (21 refs)

- 79-5201 Adenovirus Type 12 VA RNA. I. Synthesis in Productive Infection and Gene Mapping.** (Eng) Fohring, B. (Fachbereich Biologie, Universitat

Kaiserslautern, W. Germany); Geis, A.; Koomey, M.; Raska, K. *Virology* 95(2): 295-302; 1979.

Virus-associated (VA) RNA synthesized late in adenovirus type 12 (Ad12)-infected cells was analyzed by two-dimensional polyacrylamide gel electrophoresis and by a sequence of three different gel electrophoresis separations. Each of these procedures resolves two distinct VA RNA species in Ad2-infected cells; however, no minor species was detected in either the nuclei or cytoplasm of Ad12-infected KB cells. VA RNA synthesized in vitro in isolated nuclei of KB cells 18 hr after Ad12 infection also showed only one distinct species upon electrophoretic analysis. VA RNA synthesis in isolated nuclei was resistant to α -amanitin at a concentration of 1 μ g/ml, but it was inhibited by a high concentration of α -amanitin (100 μ g/ml), which indicates that Ad12 VA RNA is synthesized by RNA polymerase III. The gene for VA RNA was mapped on the Ad12 genome by blot hybridization experiments. It is located around map unit 0.30, as determined by hybridization to fragments G and H of the *Bam* HI digest of Ad12 DNA. T₁ ribonuclease oligonucleotide fingerprint analysis of RNA selected by hybridization to fragments G and H failed to provide evidence for two species of VA RNA of distinctly different structure in this adenovirus serotype. (29 refs)

- 79-5202 Comparison of Late mRNA Splicing among Class B and Class C Adenoviruses.** (Eng) Kilpatrick, B. A. (Cold Spring Harbor Lab., Cold Spring Harbor, NY 11724); Gelinas, R. E.; Broker, T. R.; Chow, L. T. *J Virol* 30(3): 899-912; 1979.

Experiments in which leader sequences for the *r*-strand late messenger RNA's (mRNA's) of class B serotype adenoviruses were mapped are described, along with experiments in which sequence relationships among the late RNA leaders of class B and class C serotypes were compared. Adenovirus class B (Ad3 and Ad7) and class C (Ad1, Ad5, and Ad6) late *r*-strand mRNA's were found to have segmented 5' leaders. These leaders were very similar among serotypes within a class, but they differed in sequence from the leaders on late mRNA's of a different class. However, the leader components of class B viruses mapped at essentially the same map coordinates as those of class C viruses. The 5' coordinates of the main bodies of class B messages to which the tripartite leaders are attached as well as the map positions of several of their early mRNA's were very similar to those of Ad2 transcripts. Infrequent examples of late *r*-strand polysomal RNA's of Ad3 and Ad7 had, in addition to the three common leader segments, a fourth leader segment derived from RNA encoded at various sites between the second and third leaders. The extra components formed several distinct groups. These molecules are presumably intermediates in the splicing processes that generate mature messages. (41 refs)

- 79-5203 Polyoma DNA Synthesis in Isolated Nuclei: Evidence for Defective Replication Forks. (Eng) Bjursell, G. (Imperial Cancer Res. Fund, Lincoln's Inn Fields, London WC2A 3PX, England); Munck, V.; Therkelsen, A. J. *J Virol* 30(3): 929-932; 1979.

A study was conducted to analyze how faithfully replication of polyoma DNA in a well-characterized nuclear system follows the bidirectional pathway. Nuclei isolated from polyoma virus-infected mouse 3T6 cells were incubated under conditions suitable for polyoma DNA synthesis. Electron microscopy and standard regression statistics showed that replication was mainly unidirectional in a large number of molecules, which indicates that inactive replication forks were present. The replication forks were inactivated randomly, and the defect seemed to be present from the beginning of the in vitro incubation. However, additional inactivation of forks might occur throughout the incubation. Each DNA segment from the origin to the terminus consisted of forks moving at different rates, and many forks passed through the termination site. Since a significant fraction of the replicative intermediates contained one impaired fork, it is suggested that two active forks are needed for proper termination. (22 refs)

- 79-5204 Structure of Polyoma Virus mRNAs Synthesized in Productively Infected Mouse Cells. (Eng) Kamen, R. (Imperial Cancer Res. Fund Labs., Lincoln's Inn Fields, P.O. Box 123, London WC2A 3PX, England); Favaloro, J.; Parker, J.; Treisman, R.; Flavell, A. J.; Cowie, A.; Legon, S. *Differentiation* 13(1): 45-46; 1979.

Recent studies of the topography of polyoma virus transcripts illustrate three principles. (1) Viral messenger RNA's (mRNA's) synthesized early in productive infection are a family of RNA's related by differential internal splicing, which allows a single continuous DNA sequence in the viral genome to encode a minimum of three different polypeptide chains; (2) viral mRNA's synthesized late in productive infection are a further family of three mRNA's related by "leader sequence transfer"; and (3) the structure of the "leader" sequences attached to the three late mRNA's demonstrates the principle of 5'-terminal heterogeneity, and it shows that posttranscriptional processing can generate tandemly repeated RNA sequences that constitute a sequence amplification with respect to the viral DNA sequence. (26 refs)

- 79-5205 Factors Affecting the Formation of Polyoma Pseudovirions. (Eng) Cashdollar, L. W. (West Virginia Univ., Morgantown, WV). *Diss Abstr Int [B]* 39(11): 5236; 1979 (no refs)

- 79-5206 Influence of Inactivated Sendai Virus on Early Events in Polyomavirus Infection of Permissive and Nonpermissive Host Cells. (Eng) Artamonova, V. (Lab. Virus Etiology Tumors, Gamaleya Inst. Epidemiology and Microbiology, Moscow, USSR); Shevliaghin, V. *Intervirology* 11(6): 351-358; 1979.

A quantitative radiochemical investigation was made of the effect of β -propiolactone-inactivated Sendai virus (SV) on early events in polyomavirus infection of permissive (mouse embryo fibroblasts) and nonpermissive (chicken and human embryo fibroblasts) cells. These experiments showed that (1) SV did not increase polyomavirus adsorption on permissive or nonpermissive cells; (2) SV induced polyomavirus elution from permissive and nonpermissive cells during the first 40 min and 6 hr postinfection, respectively; and (3) SV promoted the penetration of polyomavirus into lysosomes only in nonpermissive cells. The max amounts of radioactively labeled virion DNA and viral coat proteins were found in lysosomes at 2-3 hr postinfection. (16 refs)

- 79-5207 Cellular and C-Type Viral Factors in Infections by Polyoma Virus *hr-t* Mutants. (Eng) Goldman, E. (Dept. Medical Microbiology, Univ. California at Irvine, California Coll. Medicine, Irvine, CA 92717); Hattori, J.; Benjamin, T. *Virology* 95(2): 373-384; 1979.

The effects of endogenous cellular and C-type RNA viral factors on the growth and transforming properties of polyoma virus *hr-t* mutants were examined. Moloney murine leukemia virus (MuLV) confers a permissive state on 3T3 cells, enhancing the growth of the *hr-t* mutant NG-18. However, MuLV infection of normal rat kidney (NRK) cells does not enable NG-18 to transform these cells. Fv-1 restriction, pretreatment of cells with mitomycin C, or serum starvation after MuLV infection all prevent MuLV from inducing the permissive state in 3T3 cells. Primary mouse embryo cells, which are constitutively permissive for *hr-t* mutant growth, and primary rat or hamster embryo cells are not able to be transformed by *hr-t* mutants. These mutants are unable to induce either lectin agglutinability or transformation in a variety of mouse cells that are permissive for *hr-t* mutant growth. It thus appears that endogenous cellular factors or exogenous MuLV infections in mouse cells induce a permissive state, thereby enhancing the growth of *hr-t* mutants that are presumed to have lost the ability to induce that state. These factors act only to bypass the need for the *hr-t* function in polyoma virus growth, and they do not restore *hr-t* viral gene activity in inducing transformation and related cellular properties. The results are discussed in terms of a model proposed earlier for pleiotropic regulation of cellular factors by the *hr-t* viral gene. (31 refs)

- 79-5208 Infectivity in Mouse Fibroblasts of Polyoma DNA Integrated into Plasmid pBR322 or Lambdaoid Phage DNA. (Eng) Fried, M. (Imperial Cancer Res. Fund, Lincoln's Inn Fields, London WC2, England); Klein, B.; Murray, K.; Greenaway, P.; Tooze, J.; Boll, W.; Weissmann, C. *Nature* 279(5716): 811-816; 1979.

The construction of various plasmid pBR322 and phage λ derivatives containing polyoma (Py) DNA and the infectivity of these derivatives toward mouse fibroblast cells are reported. Hybrid plasmid molecules were made with DNA from a Py mutant that lacked an *Hha* restriction site by digestion with restriction enzymes *Eco*RI or *Bam*HI and ligation to cleaved pBR322. *Escherichia coli* HB101 was transformed with the recombinant DNA, and colonies containing Py DNA were identified by hybridization to 32 P-labeled Py RNA. Py DNA was also inserted into DNA from several bacteriophage λ derivatives. Of the Py-pBR322 hybrids joined through the *Bam*HI site, those containing one unit length of Py virus DNA gave <1 plaque-forming unit/ μ g hybrid DNA, but cleavage of the hybrids with *Bam*HI resulted in a specific infectivity similar to that of the viral DNA cleaved with *Bam*HI. Similar results were obtained with 5/6 hybrids containing monomers of Py virus DNA joined to pBR322 through the *Eco*RI cleavage site. Hybrids containing 2 or 1.9 tandem head-to-tail genomes of Py virus DNA were infectious (10% and 1% as infectious as intact form I viral DNA, respectively). Py virus was isolated from several cell cultures that had been infected with the restricted plasmid containing monomeric Py DNA or with the unrestricted plasmid containing dimeric Py DNA. The results for the infectivity of the Py- λ hybrids before and after restriction were essentially the same as those for the monomer Py-pBR322 hybrids. The fact that cloned Py DNA, when excised at the site of joining, has an infectivity very similar to that of form III DNA derived from Py virions is evidence for the remarkable fidelity of the cloning procedure and the stability of a eukaryotic sequence replicated in a prokaryotic host. (26 refs)

- 79-5209 Effect of Mitomycin C and 60 Co γ -Irradiation on the Replication of SV40 in Cell Lines of Varying Permissivity for SV40 Replication. (Eng) Rakusanova, T. (Dept. Pediatrics, St. Elizabeth's Hosp., Boston, MA 02135); Smales, W. P.; Kaplan, J. C.; Black, P. H. *J Gen Virol* 43(part 1): 235-239; 1979.

The effects of mitomycin C and 60 Co γ -irradiation, which induce production of SV40 from SV40-transformed hamster cells, on the replication of superinfecting SV40 or the virus DNA in cells varying in permissivity for SV40 replication have been examined. These agents enhance replication of SV40 in an uninducible line of SV40-transformed hamster kidney cells and in nonpermissive secondary hamster kidney cells. The same treatments do not affect SV40 replication in semipermissive hamster

(BHK21) and human (HEL, HEK) cells and inhibit SV40 replication in permissive monkey (TC-7) cells. It is concluded that forms of induction treatment, such as mitomycin C or 60 Co γ -irradiation, modify the expression of host cell factors which determine the level of permissivity for SV40 infection. (9 refs)

- 79-5210 Effect of Azacytidine in SV40-Infected BSC-1 Cells. (Eng) Reuveni, Y. (Dept. Microbiology, Vincent T. Lombardi Cancer Center, Georgetown Univ., Sch. Medicine, Washington, DC 20007); Rosenthal, L. J. *Intervirology* 11(3): 191-195; 1979.

The effect of 5-azacytidine (5-AC, 25-300 μ g/ml) on simian virus 40 (SV40) messenger RNA transcription was studied following treatment of SV40-infected BSC-1 cells. The ribosomal 28S and 18S RNA's decreased with increasing 5-AC concentration, maximal inhibition occurring at 200-300 μ g/ml. After treatment with 200 μ g/ml 5-AC for 2 hr, virus-specific RNA in the 19S and 16S RNA region increased from 3.6% to 28%-36%. This was due to a 70%-75% reduction in ribosomal RNA's in the cytoplasm of the infected cells. (9 refs)

- 79-5211 Functional Characterization of the Early and Late mRNAs of Simian Virus 40. (Eng) Hunter, T. (Tumor Virology Lab., Salk Inst., P.O. Box 1809, San Diego, CA 92112). *Virology* 95(2): 511-522; 1979.

Early simian virus 40 (SV40) messenger RNA's (mRNA's) were characterized by size fractionation on acrylamide gels followed by in vitro translation and immunoprecipitation. The mRNA for the 17,000-dalton (17K) tumor (T) antigen migrated more slowly than that for the 100K T antigen, with the apparent size difference being 250 nucleotides. This finding is consistent with the mRNA for the 17K T antigen corresponding to an almost complete copy of the early region; the mRNA for the 100K T antigen probably lacks the sequences between 0.59 and 0.54 map units. The synthesis of any antigen intermediate in size between the 100K and 17K T antigens could not be detected by translation of SV40-specific RNA followed by immunoprecipitation. The synthesis of two proteins from intracellular SV40-specific mRNA's was demonstrated. They appeared to be identical to the VP2 and VP3 found in the virion on the basis of their mobilities in acrylamide gels and their tryptic peptide maps. Both VP2 and VP3 were labeled with formyl-[35 S]methionine when synthesized in the presence of [35 S]fMet-tRNA^{fMet}. When the partial proteolysis products of these N-terminally labeled proteins were analyzed, it was shown that VP2 and VP3 shared common C termini. Therefore, VP3 is initiated and made independently of VP2 and is not derived from VP2 by proteolytic processing. VP2 and VP3 are both made from mRNA's about 19S in

size. The mRNA for VP2 migrated marginally more slowly than the mRNA for VP3 in acrylamide gels. (38 refs)

- 79-5212 Nucleotide Sequence Analysis of Two Simian Virus 40 Mutants with Deletions in the Region Coding for the Carboxyl Terminus of the T Antigen. (Eng) Van Heuverswyn, H. (Lab. Molecular Biology, State Univ. Ghent, B-9000 Ghent, Belgium); Cole, C.; Berg, P.; Fiers, W. *J Virol* 30(3): 936-941; 1979.

The nucleotide sequence of two simian virus 40 early mutants, *d11263* and *d11265*, which lack a DNA segment around map positions 0.21 and 0.18, respectively, was analyzed. To characterize these deletions at the nucleotide level, each mutant DNA was digested separately with the restriction endonucleases *Hind*III + *I*II, *Hae*III, and *Alu*I. In-phase deletions of 33 nucleotide pairs for *d11263* and 39 nucleotide pairs for *d11265* were found. The 33-base pair deletion in *d11263* did not account for the apparent 6,000-dalton reduction in size observed for the large tumor (T) antigen induced by this mutant. In *d11265*, the normal termination signal as well as most of the proline-rich terminal tryptic peptide had been removed, and the carboxyl terminus of the mutant T antigen was a series of three cysteine residues. (21 refs)

- 79-5213 Nucleotide Sequence Analysis of Viable Deletion Mutants Lacking Segments of the Simian Virus 40 Genome Coding for Small t Antigen. (Eng) Thimmappaya, B. (Dept. Microbiology, Univ. Connecticut Health Center, Farmington, CT 06032); Shenk, T. *J Virol* 30(3): 668-673; 1979.

Direct DNA sequence analysis was used to map the deletions in nine viable simian virus 40 mutants. The mutant DNA's lack small segments of the early region of the viral chromosome (between 0.535 and 0.600 map units). The deletions are all located in the region that is removed from the large tumor (T)-antigen transcript by splicing. No one deletion removes this entire region, but no part of this segment is conserved in all of the mutants except for several nucleotides near the splice points of the transcript. Although the deletions do not alter the region coding for the large T polypeptide, they do delete portions of the segment coding for the C-terminal half of the small t polypeptide. (20 refs)

- 79-5214 Nucleotide Sequence Deletions Within the Coding Region for Small-t Antigen of Simian Virus 40. (Eng) Volckaert, G. (Lab. Molecular Biology, State Univ. Ghent, B-9000 Ghent, Belgium); Feunteun, J.; Crawford, L. V.; Berg, P.; Fiers, W. *J Virol* 30(3): 674-682; 1979.

Simian virus 40 early mutants with deletions mapping in the 0.53-0.60 region were sequenced by the Maxam and Gilbert approach. All these deletions affect the small tumor (t) gene. The size of the shortened small t-related polypeptides produced by several of the mutants was compared with the mol wt, as deduced from the nucleotide sequence. There was good agreement for the mutants *d890*, *d891*, and *d12102*. For *d12121* and *d12122*, the small t-related protein was considerably larger than expected. It is possible to explain this result on the basis of the nucleotide sequence: the normal splicing event of the small t messenger RNA (mRNA) still occurs, but as the deletion shifts the reading frame, translation of the small t-related polypeptide continues beyond the small t splice, but in a different reading frame than that for large T antigen. Mutants *d883*, *d884*, and *d12112* have lost one of the small t splicing boundaries, and no (or minute amounts of) small t-related protein was observed in mutant-infected cells. There may be a relationship between splicing and transport of polyadenylic acid-containing mRNA from the nucleus to the cytoplasm in vertebrate cells. (31 refs)

- 79-5215 Simian Virus 40 Mutants with Deletions at the 3' End of the Early Region Are Defective in Adenovirus Helper Function. (Eng) Cole, C. N. (Dept. Human Genetics, Yale Univ. Sch. Medicine, New Haven, CT 06510); Crawford, L. V.; Berg, P. *J Virol* 30(3): 683-691; 1979.

The ability of viable mutants of simian virus 40 (SV40) that contain deletions at various sites in the viral DNA to enhance adenovirus type 2 (Ad2) growth in CV-1 monkey cells was examined. Only mutants with deletions near the 3' end of the early region were deficient in providing this helper function. Mutants *D11265*, lacking 39 base pairs at map position 0.18, and *D11263*, lacking 33 base pairs at map position 0.20, were approx 4% and 30% as effective as wild-type SV40, respectively. The extent of enhancement of Ad2 yield depended on the multiplicity of infection by SV40, but not by Ad2 (at a multiplicity of infection of ≤ 50), as well as on the relative times of infection by Ad2 and SV40. Increasing the SV40 multiplicity of infection or infecting cells with SV40 wild type or mutants prior to Ad2 infection increased the Ad2 yield dramatically. The tumor (T) antigens of wild-type SV40, *D11263*, and *D11265* were examined. An attempt was made to correlate defects in helper function, alterations in the T-antigen structure, and the DNA sequence of the mutants as determined previously. (42 refs)

- 79-5216 T-Antigen Expression in Proliferating and Non-proliferating Simian Virus 40-transformed Mouse Cells. (Eng) Zouzas, D. (Dept. Pathology, New York Univ. Sch. Medicine, New York, NY 10016); Basilico, C. *J Virol* 30(3): 711-719; 1979.

Temperature-sensitive simian virus 40-transformed mouse 3T3 cells (ts SV3T3 cells) were used to study the expression of the viral genome under proliferating and non-proliferating conditions, in the presence and absence of inhibitors of macromolecular synthesis and of the tumor promoter phorbol myristate acetate. These cells express the transformed phenotype at 32 C and lose most or all of their transformed growth characteristics at 39 C. ts SV3T3 cells that were growth-arrested at 39 C by low serum concentration or saturation density accumulated in G1 and did not express tumor (T) antigen. When these cells were induced to proliferate at either 32 or 39 C, T-antigen synthesis preceded the entry of the cells into the S phase, and it was not coupled to DNA replication. G1-arrested ts SV3T3 cells were induced to synthesize T antigen by phorbol myristate acetate treatment (0.1 µg/ml, but antigen synthesis was not followed by cellular DNA synthesis. This suggested that T antigen may act as an inducer of cell proliferation, rather than as a direct initiator of DNA replication. Isoleucine deprivation arrested the growth of the ts SV3T3 cells, but these cells, as well as normal 3T3 cells, did not accumulate in G1 and they continued to express T antigen. The temperature-sensitive expression of the transformed phenotype in the ts SV3T3 cells does not appear to be due to a lack of transcription of specific regions of the integrated simian virus 40 genome at 39 C. (40 refs)

- 79-5217 Biology of Simian Virus 40 (SV40) Transplantation Antigen (TrAg). IV. Inhibition by Human Interferon of Expression of SV40 TrAg in SV40-infected Monkey Cells. (Eng) Tevethia, S. S. (Dept. Microbiology, Pennsylvania State Univ. Coll. Medicine, Hershey, PA 17033); Greenfield, R. S.; Rieder, V.; Tevethia, M. J. *Virology* 95(2): 587-592; 1979.

Treatment of African green monkey kidney cells with human interferon prior to simian virus 40 (SV40) infection inhibited the expression of SV40 transplantation antigen (TrAg) as well as tumor (T) antigen. The inhibition occurred in SV40-infected but not in SV40-transformed monkey cells. The synthesis of SV40 T antigen as detected in the indirect immunofluorescence test and of large and small T antigens as detected by immunoprecipitation with sera from tumor-bearing hamsters and electrophoresis in sodium dodecyl sulfate-gels was similarly affected in SV40-infected monkey cells. These results suggest that the induction of SV40-specific TrAg in the cytolytic cycle depends upon a viral, rather than a host, message. (26 refs)

- 79-5218 Biochemical and Immunochemical Characterization of Two Simian Virus 40 (SV40)-specific Glycoproteins in Nuclear and Surface Membranes of SV40-transformed Cells. (Eng) Schmidt-Ullrich, R. (Therapeutic Radiology Dept., Radiobiology Div., Tufts-New England Medical Center, 171 Harrison

Ave., Boston, MA 02111); Thompson, W. S.; Wallach, D. F. *Biochem Biophys Res Commun* 88(3): 887-894; 1979.

Biochemical and immunochemical techniques were used to characterize the membrane proteins of simian virus 40 (SV40)-transformed cells. The plasma membranes of several SV40-transformed cells contained virus-specific proteins with mol wts of approx 100,000 and 60,000 daltons and isoelectric points of approx 4.7 and 4.5, respectively. Triton X-100 extracts of purified nuclei from SV40-transformed hamster lymphocytes contained the same proteins but in different proportions, the high mol wt component being increased sixfold compared with the lower mol wt one. Both proteins could be labeled metabolically with [¹⁴C]glucosamine and their isoelectric points could be altered by neuraminidase treatment, which indicates that they are sialoglycoproteins. - 79-5220 Differences in the Surface Components of Normal and SV-40 Transformed 3T3 Mouse Fibroblasts. (Eng) Sherbet, G. V. (Cancer Res. Unit, Univ. Dept. Clinical Biochemistry, Royal Victoria Infirmary, Newcastle upon Tyne NE1 4LP, England); Lakshmi, M. S. *Exp Cell Biol* 47(1): 61-70; 1979.

Differences in the surface components of 3T3 mouse fibroblasts and their simian virus 40-transformed counterparts were determined by isoelectric equilibrium analysis. The net negative surface charge density of the transformed cells appeared to be marginally lower than that of the untransformed cells. Studies in which the surface amino groups were modified with formaldehyde indicated that about 30% more cationic groups were present on the transformed cells; ie, the latter contain some additional basic material not detectable on the surface of normal cells. Ionization of the cationic groups in the transformed cells was inhibited by the strongly acidic carboxylic groups. This indicates that there is a distribution of extra cationic material in the vicinity of acidic glycoprotein components on the surface. The investigation also revealed that unidentified anionic groups that ionize at high pH are present on the transformed cells. The density of these groups, which appeared to be thiol groups, was 33% higher in the transformed cells than in the normal cells. (33 refs)

- 79-5221 The Emergence of Simian Virus 40 Variants in a Persistent Infection of Rhesus Monkey

Kidney Cells and Their Interaction with Standard Simian Virus 40. (Eng) Norkin, L. C. (Dept. Microbiology, Univ. Massachusetts, Amherst, MA 01003). *Virology* 95(2): 598-603; 1979.

The emergence of defective interfering (DI) variants of simian virus 40 (SV40) in LLC-MK₂ rhesus monkey kidney cells persistently infected with SV40 was studied. DI particles were first detected at 6 wk, were not detected at 7 and 8 wk, and were usually present from 9 wk on. DI particle production tended to parallel the number of cells producing plaque-forming units (PFU). Homologous interference by SV40 DI particles was not an all-or-none phenomenon and was the result of a competitive interaction with standard virus during replication. Preinfection with DI particle-containing stocks followed after 24 hr by superinfection with standard virus resulted in greater levels of interference than simultaneous coinfection, but there was no interference when cells were superinfected with carrier culture stock 24 hr after infection with standard virus. Most of the particles in the carrier culture stocks were not able to produce capsids (V antigen), the fraction of V-antigen-producing cells being somewhat reduced and the PFU yield being reduced by 20-fold in mixed infections. Coinfection of SV40 DI particle-infected cells with vesicular stomatitis virus (VSV) did not result in interference with VSV replication. Almost coincident with the emergence of DI particles, the population of standard large plaque virus was gradually replaced by virus which produced small, but equally cytopathic, virus. The uncloned carrier culture virus became temperature sensitive between 14 and 28 wk. There were changes in restriction endonuclease fragments of the carrier culture viral DNA by 2 wk, but most of the fragments were still indistinguishable from standard virus fragments at 57 wk. (22 refs)

79-5222 Intranuclear Particles in Keratoacanthoma: Possible Association with Malignant Degeneration. (Eng) Van De Staak, W. J. (Dept. Dermatology, Univ. Nijmegen, Javastraat 104, Nijmegen, Netherlands); Bergers, A. M. *Dermatologica* 158(6): 413-416; 1979.

An electron microscope investigation of keratoacanthomas from 12 patients is reported. Intranuclear viruslike particles (400-800 nanometers) were seen in three cases; two of these subsequently underwent malignant transformation to squamous cell carcinomas. These findings suggest that it is particularly important to exclude the possibility of malignant change in those tumors containing intranuclear particles. (12 refs)

79-5223 Intracisternal A Particles in Preimplantation Embryos of Feral Mice (*Mus musculus*). (Eng) Calarco, P. G. (Dept. Anatomy, Univ. California, San Francisco, CA 94143). *Intervirology* 11(6): 321-325; 1979.

Preimplantation embryos of feral mice (*Mus musculus*) were examined for expression of intracisternal A particles (IAP) using electron microscopy. IAP were not observed in zygotes, but at the two-cell stage large numbers of IAP were seen budding into the endoplasmic reticulum (ER), and a morphology characteristic of the very early stages of IAP formation was observed. Small amounts of crystalloid material were first seen at the two-cell stage. At the four- and eight-cell and morula stages there was a dramatic decrease in IAP with no apparent areas of budding IAP. There appeared to be more crystalloid material at these later stages. Very few IAP were seen within the ER at the blastocyst stage. At all stages the IAP had an outer shell diameter of approx 70 nanometers (nm) and an inner shell diameter of approx 33 nm. (23 refs)

79-5224 Use of the Transfection Assay to Detect Virus-specific Information in Human Tumor DNA. (Rus) Kniazev, P. G. (Lab. Biochemistry, Petrov Res. Inst. Oncology, Leningrad, USSR); Perevozchikov, A. P.; Korobitsyn, L. P.; Zhudina, A. I.; Kuznetsov, O. K.; Savost'ianov, G. A.; Diad'kova, A. M.; Seits, I. F. *Vopr Onkol* 25(5): 50-55; 1979.

An attempt was made to determine whether the DNA from human tumors contains virus-specific information. DNA specimens were isolated from the blood of a patient with myeloid leukemia (ML) and from specimens of pleomorphic cell rhabdomyosarcoma, synovial sarcoma, and neurinoma. The DNA specimens were then used to transfect diploid human embryo lung (HEL) cells; oncornavirus replication was determined by the radioisotope method. Of 10 cultures of HEL cells infected with DNA from the peripheral blood of the ML patient, 2 started to produce RNA-containing particles with a buoyant density of 1.16-1.18 g/ml. A sediment of the cultures that produced these particles showed reverse transcriptase activity. Electron microscope examination of culture fluid specimens from the 1.16- to 1.18-g/ml zone did not show particles typical of C-type oncornaviruses. The rhabdomyosarcoma, synovial sarcoma, and neurinoma specimens increased the proliferative activity of the HEL cells, but they did not produce viruslike particles. (11 refs)

79-5225 Nonrandom Correlation Between Selective Distribution of Virogenic 5-Bromodeoxyuridine and DNA-binding Nonhistone Proteins in Rat DNA. (Eng) Schwartz, S. A. (Dept. Pathology, Univ. Chicago, Chicago, IL 60637). *Exp Cell Biol* 47(3): 172-182; 1979.

In an attempt to elucidate further the molecular mechanism involved in the bromodeoxyuridine (BUdR)-mediated activation of endogenous C-type virus from normal rat embryo cells, nonhistone nuclear protein-DNA interactions

were analyzed in vitro. Native and kinetically fractionated DNA samples previously labeled with either [³H]-thymidine or [³H]-BUdR were combined with DNA-binding nonhistones and characterized according to isotope distribution and extent and localization of protein-binding sites. As in previous studies, [³H]-BUdR was relatively more concentrated in repetitive DNA, compared with [³H]-thymidine. In a membrane filter retention assay, nearly 60% of complete, 37% of repetitive, and 12% of nonrepeated DNA-protein reconstituted complexes were retained on the filters regardless of the isotopic precursor. However, a proportionately greater amount of [³H]-BUdR than [³H]-thymidine was recovered following extensive digestion of renatured complexes with DNase I, even though comparable amounts of DNA were acid-insoluble. The disproportionate binding of nonhistones to repetitive DNA, especially BUdR-substituted regions, may be related to the highly specific, well-characterized modifications in eukaryotic transcription attributed to the analog. (31 refs)

- 79-5226 Search for a New Antigen Associated with Oncornavirus D in Human Breast Cancer Cells. (Rus) Kosiakov, P. N. (D. I. Ivanovskii Inst. Virology, Moscow, USSR); Korosteleva, V. S.; Pavliuchenkova, R. P.; Kosiakova, N. P.; Nabokov, Iu. S.; Mogilevskii, I. L.; Kulakova, A. M. *Vopr Virusol* (3): 247-251; 1979.

This study was designed to verify whether the tissue of human benign and malignant breast tumors contains antigens associated with oncornavirus D. Surgical specimens obtained from 54 patients with breast cancer and 17 patients with benign breast lesions (8 fibroadenomas and 9 mastopathies) were assayed by a complement-fixation reaction using rabbit antisera to oncornavirus D-associated antigens extracted from tissue cultures of human malignant I-96 or HEP-2 cells. The antigen was detected in 9/54 breast cancer specimens at a titer of 1:80-1:160, compared with 1:1,280-1:2,560 in HEP-2 or I-96 cells; all 17 specimens of benign lesions were free of antigen. (13 refs)

- 79-5227 Intracellular Sodium and Potassium Concentrations and the Regulation of Gene Expression in Lytic Virus-infected and Virus-transformed Chick Cells. (Eng) Garry, R. F. (Univ. Texas, Austin, TX). *Diss Abstr Int [B]* 39(11): 5238-5239; 1979 (no refs)

- 79-5228 Antiviral Antibody Reacting on the Plasma Membrane Alters Measles Virus Expression Inside the Cell. (Eng) Fujinami, R. S. (Dept. Immunopathology, Scripps Clinic and Res. Foundation, La Jolla, CA 92037); Oldstone, M. B. *Nature* 279(5713): 529-530; 1979.

Experiments demonstrating that measles virus antibodies added to virus-infected HeLa cells decrease the amount of both viral structural polypeptide hemolysin expressed on the cell surface and a structural polypeptide (measles virus phosphoprotein) found inside the cell are presented. These observations indicate that antibody directed against an antigen on the cell surface can interfere with viral proteins expressed inside the cell. (18 refs)

- 79-5229 Reconstitution of Membranes with Individual Paramyxovirus Glycoproteins and Phospholipid in Chololate Solution. (Eng) Hsu, M. C. (Rockefeller Univ., New York, NY 10021); Scheid, A.; Choppin, P. W. *Virology* 95(2): 476-491; 1979.

A method for reconstituting biologically active membranes with individual Sendai virus glycoproteins (HN and F) and phosphatidylcholine is described. The glycoproteins were isolated in the presence of Triton X-100 and transferred into chololate soln by sedimentation into a sucrose gradient containing 2% chololate. The membranes were then reconstituted with HN or F and phosphatidylcholine by removal of the chololate through the use of dialysis. Experiments with radioactively labeled detergents showed that the removal of Triton X-100 by sedimentation into chololate and the removal of chololate by dialysis were essentially complete. With the F protein, vesicles 400-800 Å in diameter and filaments 600-800 Å long were formed, depending on the proportions of lipid and protein in the initial mixture. Both structures were covered with glycoprotein spikes. With the HN protein, only vesicles were formed, and the densities of the spikes on the surface were dependent on the initial lipid to protein ratio. Membranes reconstituted from HN protein exhibited hemagglutinating and neuraminidase activities. Reconstituted particles containing the F protein exhibited hemolytic activity when a mechanism was provided to attach the F protein-lipid complex to the cell; ie, by the addition of wheat germ agglutinin. These results confirm the role of F protein in membrane fusion and show that the requirements for F protein activity are the previously demonstrated proteolytic processing of F, the insertion of F protein into lipid, and the presence of an attachment mechanism. (33 refs)

- 79-5230 Use of UV Irradiation to Identify the Genetic Information of Vesicular Stomatitis Virus Responsible for Shutting Off Cellular RNA Synthesis. (Eng) Weck, P. K. (Dept. Microbiology, Univ. Virginia Sch. Medicine, Charlottesville, VA 22908); Carroll, A. R.; Shattuck, D. M.; Wagner, R. R. *J Virol* 30(3): 746-753; 1979.

The involvement of viral RNA and protein synthesis in the inhibition of host RNA metabolism was examined. UV irradiation of infectious vesicular stomatitis virus (VSV) was

employed to study the relationship between the expression of certain viral gene functions and viral inhibition of RNA synthesis in mouse myeloma (MPC-11) cells. Viral infectivity, protein synthesis, and viral messenger RNA synthesis were all highly susceptible to inactivation by UV radiation; however, low levels of viral transcriptase activity were detected in vitro in virus preparations subjected to large doses of UV radiation. In sharp contrast, the capacity of VSV to shut off cellular transcription was quite resistant to UV radiation. The data indicate that viral transcription is essential for the inhibition of host RNA metabolism, even though the synthesis of viral polypeptides in the inhibited cells could not be detected. At levels of UV radiation that inactivated all viral gene functions, except viral inhibition of cellular RNA synthesis, the only viral product detected was nonadenylated, low-mol-wt RNA species. (20 refs)

- 79-5231 Recovery of Three Distinct Biologically Active Type C Viruses from Cloned C57Bl/6 Melanoma Cells. (Eng) Levy, J. A. (Cancer Res. Inst., Univ. California Sch. Medicine, San Francisco, California 94143); Rutledge, F.; Dimpfl, J.; Silagi, S. *J Gen Virol* 43(2): 283-288; 1979.

The B16 C57Bl/6 melanoma cell line was cloned, and the 25 clones obtained were examined for melanin and virus production. One clone, 20282 E-7, that produced substantial amounts of melanin but no infectious virus, was selected, treated with 30 µg/ml iododeoxyuridine (IdUrd), and then cultured alone or overlaid with either NIH-ME, BALB-ME, human foreskin, or mink lung cells. Control cells of this clone, not treated with IdUrd, were cultured in the same manner. After weekly passages for 3 wk, the cells were examined for ecotropic and xenotropic virus production. Control cultures did not release ecotropic or xenotropic viruses. IdUrd-treated cells cultured alone produced a B-tropic virus, as determined by its preference for BALB-ME cells. Supernatants from IdUrd-treated cells cocultivated with NIH-ME cells were inoculated at different dilutions onto fresh NIH-ME cells every 7 days for 2-3 wk, which resulted in the isolation of a pure N-tropic virus that grew preferentially in NIH-ME cells and could not be passed through BALB/c-ME cells. From this same melanoma clone, a B-tropic virus free of N-tropic virus was obtained by selectively inoculating the supernatant from IdUrd-treated cells onto BALB-ME cells for several passages. A xenotropic murine leukemia virus (MuLV) was also isolated by treating the clone cells with IdUrd and cocultivating them with mink lung cells for four passages. Upon cocultivation with NRK-Harvey cells, the mink cells yielded a xenotropic virus pseudotype of murine sarcoma virus. Evidence of the X-tropic virus envelope was demonstrated by specific neutralization with rabbit anti-X-tropic virus antiserum and normal mouse sera. These same cells, if treated with IdUrd, produced a B-tropic virus.

After seven passages, the melanoma clone produced the B-tropic virus spontaneously but not the xenotropic virus. At this time, the cells were less pigmented than the nonvirus producing parental cell line. IdUrd-induced virus production in melanoma cells was accompanied by a reduction in melanin production. Puromycin and cycloheximide treatment of melanoma cells decreased melanin production to a lesser extent than did IdUrd treatment. Acute infection of the non-virus-producing melanoma cells by ecotropic MuLV caused a noticeable decrease in melanin production concomitant with virus replication in the cells. These findings confirm earlier reports that MuLV production by differentiated melanoma cells is associated with a decrease in melanin production. (21 refs)

- 79-5232 Neuroblastoma Cell Fusion by a Temperature-sensitive Mutant of Vesicular Stomatitis Virus. (Eng) Hughes, J. V. (Div. Biology, Kansas State Univ., Manhattan, KS 66506); Dille, B. J.; Thimmig, R. L.; Johnson, T. C.; Rabinowitz, S. G.; Dal Canto, M. C. *J Virol* 30(3): 883-890; 1979.

Data concerning the fusion of neuroblastoma cells by a temperature-sensitive mutant of vesicular stomatitis virus (*ts*G31) that does not mature properly when grown at 39 C are presented. *ts*G31 promoted extensive fusion of murine neuroblastoma cells at this nonpermissive temperature. Polykaryocytes (PKC's) apparently formed as a result of fusion from within the cells, which requires low doses of infectious virions for its promotion and is dependent on viral protein synthesis. Although 90% of infected N-18 neuroblastoma cells were fused by 15 hr after infection, larger PKC's continued to form, leading to an av of 28 nuclei per PKC as a result of PKC's fusing to each other. Two neuroblastoma cell lines underwent fusion, whereas three other cell lines (BHK-21, CHO, and 3T3) were incapable of forming PKC's, suggesting that nervous system-derived cells are particularly susceptible to vesicular stomatitis virus-induced fusion. Although the normal assembly of the protein components of this virus was deficient at 39 C, the G glycoprotein was inserted into the infected cell membranes at this temperature. Two lines of evidence suggest that the expression of G at the cell surface promotes this PKC formation: (1) inhibition of glycosylation, which may be involved in the migration of the G protein to the cellular plasma membranes, inhibits cell fusion; (2) addition of antiserum directed toward the purified G glycoprotein also inhibits cell fusion. (28 refs)

- 79-5233 Carcinoma of the Vulva Arising in Condylomata Acuminata. (Eng) Shafeek, M. A. (49 Giza St., Giza, Cairo, Egypt); Osman, M. I.; Hussein, M. A. *Obstet Gynecol* 54(1): 120-123; 1979.

The case of a 30-yr-old woman with a squamous cell carcinoma of the vulva arising in condylomata acuminata is presented. The patient was much younger than most patients with vulvar carcinomas. The vulvar growth was first noted during pregnancy, and it continued to grow and enlarge following delivery. Malignancy appeared to develop after a relatively short time. It is sometimes difficult to distinguish vulvar condylomata acuminata from carcinoma on the basis of clinical evidence alone. It is, therefore, mandatory in doubtful cases to take multiple biopsies from the lesion before treatment is instituted. (15 refs)

IMMUNOLOGY

79-5234 Some Perspectives on the Transfer of Cell-mediated Immunity by Immune-RNA. (Eng)

Dray, S. (Dept. Microbiology and Immunology, Univ. Illinois at Medical Center, 835 S. Wolcott, Chicago, IL 60612); Braun, D. P. *Mol Cell Biochem* 25(1): 15-31; 1979.

RNA extracts of lymphoid cells from immune hosts, including humans, monkeys, guinea pigs, and mice, were used to transfer in vivo and in vitro cell-mediated immune reactivity to a variety of antigens. The in vivo immune responses transferred by RNA included the delayed cutaneous hypersensitivity reaction to fungal and chemically defined antigens and the tumor-rejection reaction to guinea pig hepatoma antigens. The in vitro immune responses transferred by RNA included macrophage migration inhibition by fungal, chemically defined, and tumor antigens. The transfer activity of the RNA preparations was contained in the 8S to 18S species of RNA, and it was sensitive to RNase but not to DNase or trypsin. Antigen was not detectable in the RNA preparations, and it appeared to have no role in the transfer activity. Syngeneic, allogeneic, or xenogeneic sources of RNA could transfer immune reactivity. In each system tested, the transfer of cell-mediated reactivity by RNA was specific for the antigen used to sensitize the RNA donor. Prospects for the further application of immune RNA are explored. 79-5235 Immunological Resistance to Growth of Tumours in Syngeneic Multiparous Mice. (Eng)

Chandradasa, K. D. (Dept. Immunology, Univ. Liverpool, Liverpool, England); Barnes, R. M. *Eur J Cancer* 15(5): 671-677; 1979.

Investigations were undertaken to seek direct evidence for an immunological link between the experience of pregnancy and tumor rejection in mice. The hypothesis that BALB/c mice that have experienced a pregnancy are rendered immune to a 3-methylcholanthrene-induced syngeneic tumor (MC677) was tested by direct tumor cell challenge of multiparous mice and by cell-transfer assays using purified T cells obtained from the spleens of multiparous mice. Controls were virgin BALB/c mice of the same age. The results showed that mice that had experienced a single multiparous pregnancy were resistant to the growth of MC677. In addition, purified splenic T cells from multiparous mice inhibited tumor growth following implantation of a mixture of tumor cells and splenic T cells into normal recipient mice. Age-matched virgin controls

did not show resistance to tumor growth following challenge, and their lymphoid cells were not inhibitory to tumor cells. These results demonstrate clearly that pregnancy in mice confers a degree of transplantation resistance against syngeneic tumors, and they suggest that certain membrane-expressed oncofetal antigens are operative in tumor resistance. They also provide support for a possible immunological link between a decreased risk of breast cancer and early pregnancy in humans. (17 refs)

79-5236 Tumour Production by HSV-2 Transformed Lines in Rats and the Varying Response to Immunosuppression. (Eng) Macnab, J. C. (MRC Virology Unit, Inst. Virology, Church St., Glasgow G11 5JR, Scotland). *J Gen Virol* 43(part 1): 39-56; 1979.

Rat embryo cells transformed by two temperature-sensitive (*ts*) mutants of herpes simplex virus (HSV)-2 strain HG 52 and also by ultraviolet-irradiated HSV-2 strain 333 were inoculated into highly inbred host rats, which were either newborn or had undergone various immunosuppressive treatments. The latent period before a palpable tumor (a fibrosarcoma) was detected varied directly with the degree of immunosuppression of the host. Transformed cells could form tumors after a latent period of nearly 2 yr. All tumors were invasive and in some cases metastatic. The continuing expression of HSV information in 10 tumor cell lines was demonstrated by perinuclear and cytoplasmic staining in immunofluorescence studies using a rat antiserum directed against the early polypeptides of HSV-2 HG 52 infection and a rabbit serum prepared against a 24 hr cell infection with HSV-2 HG 52 *ts* 1. Sera from tumor-bearing rats fluoresced the surface of unfixed human or rat embryo cells 4-5 hr after infection with HSV-2 HG 52. In addition, the rabbit antiserum (4740 or 4741) fluoresced the surface of 80% of the tumor cells in culture. After 20 passages in vitro, transplanted tumors taking up to a year to form a tumor in a host rat also showed specific HSV cytoplasmic and perinuclear fluorescence in tests with the rat antiserum directed against early polypeptides of HSV-2 lytic infection. (28 refs)

79-5237 Effect of Rabbit Strain on Activity Level and Cytotoxicity of Serum Complement. III. Comparison of Four Tumor Target Cells. (Eng) Fox, R. R. (Jackson Lab., Bar Harbor, ME 04609); Cherry, M.; Shultz, K. L.; Salvatore, K. J. *J Hered* 70(2): 109-114; 1979.

The effects of rabbit strain on the activity and cytotoxicity of serum complement were determined in several murine tumor cell test systems, and the results were compared with those obtained previously using lymph node cells. Serum samples from 10 males and 10 females from each of 15 genetically defined strains of rabbits and from one hybrid were tested as sources of complement for the microtiter lymphocytotoxicity test using SaI-A, 6C3HED-A, BW5147, and L cells as target cells. The tumor cells were tested with appropriate H-2 antisera. Strain differences were particularly evident when the target cells were 6C3HED-A or L cells. BW5147 cells worked well with complement from most rabbit strains, but SAI-A cells were extremely refractory and few, if any, strains provided a good source for this test system. Rabbit strains IIIC/J, IIIVO/J, and the F₁ hybrid between them were among the six best strains when tested against the tumor cells and against the lymph node cells. Strain WH/J which carries the gene (*ha*) for hereditary lymphosarcoma, proved to be a good complement source with SaI-A and 6C3HED-A, both sarcomatous in nature. However, it was not a good complement source with BW5147, a lymphatic leukemia, or L cells. This is possible evidence for the presence of a common tumor antigen associated with lymphosarcoma in both the mouse and the rabbit. (19 refs)

- 79-5238 Structural Evidence for Independent Joining Region Gene in Immunoglobulin Heavy Chains from Anti-galactan Myeloma Proteins and its Potential Role in Generating Diversity in Complementarity-determining Regions. (Eng) Rao, D. N. (Lab. Cell Biology, NCI, Bethesda, MD 20205); Rudikoff, S.; Kruttsch, H.; Potter, M. *Proc Natl Acad Sci USA* 76(6): 2890-2894; 1979.

The variable region sequences of four heavy chains from $\beta(1-6)$ D-galactan-binding myeloma proteins were determined. Two of these proteins are identical to position 100, which is located in the third complementarity-determining region (CDR-3). The remaining two differ at a total of eight positions over the first 100 amino acids, and all of the differences can be explained by single-base mutations at the DNA level. When an assessment is made of the protein segment following CDR-3, which has been termed "J segment" or "FR4," a completely different pattern of variation is observed. The J segments from the four proteins can be divided into two sets. Members of each set share a series of linked amino acids not found in members of the alternative set. The two proteins identical to position 100 have J segments from the two different sets, suggesting that recombination has occurred between *V* and *J* genes. An examination of the CDR-3 sequences from the four heavy chains revealed substitutions at positions 100 and 105. Gly is found at 100 in two of the proteins and His in the remaining two. In the two proteins with Gly-100, the following J sequence is limited to one of the two sets of J segments defined by linked amino acids. Similarly, the two heavy

chains with His-100 have J segments from the second set. Thus, at the protein level, an apparent association is seen between CDR-3 and the J segment. If CDR-3 should be found linked to the J segment at the DNA level, a new mechanism would be introduced for increasing antibody diversity by recombining various *CDR-3* plus *J* genes with genes coding for the remainder of the variable region. Alternatively, if CDR-3 were coded for by the *V* gene, then the recombination of *V* with *J* may provide an opportunity to introduce mutations in *CDR-3*. In this case, the linkage of amino acids in CDR-3 and the J segments would suggest that recognition signals are used such that certain *V* genes only pair with a given *J* gene. (23 refs)

- 79-5239 A Multi-faceted Approach to Characterization and Isolation of Immune Complexes. (Eng) Morgan, A. C. (Baylor Coll. Medicine, Houston, TX); Rossen, R. D.; Challand, B. J.; Twomey, J. J.; Hersh, E. M. *Protides Biol Fluid Proc Colloq* 26: 131-136; 1978.

An attempt was made to identify tumor-reactive antibodies and other proteins present in 2.7% polyethylene glycol precipitates obtained from selected cancer patients and normal controls. Sera from patients with malignant melanoma and colon cancer contained 12S-19S complexes that, when dissociated at pH 2.9, released proteins that sedimented at 3.0S-5.0S and bound specifically to cultured tumor cells. Sera from most normal donors contained 25S complexes that were dissociated by affinity chromatography on heat-aggregated IgG-Sepharose into a 7S IgG cytotoxin that was reactive with malignant melanoma cells and an antiglobulin that blocked the antigen-combining activity of the cytotoxin. Thus, soluble immune complexes may be found in the sera of both cancer patients and normal donors. In the complexes from the cancer patients, however, the immunoglobulin in the complex may have undergone partial proteolysis before or during characterization. (15 refs)

- 79-5240 Milk Precipitins and Circulating Immune Complexes in Selective IgA Deficiency. (Eng) Cunningham-Rundles, C. (Memorial Sloan-Kettering Cancer Center, New York, NY 10021); Brandeis, W. E.; Good, R. A.; Day, N. K. *Protides Biol Fluid Proc Colloq* 26: 137-140; 1978.

Milk precipitins and circulating immune complexes were investigated in 15 patients with selective IgA deficiency and 7 patients with malignancies and IgA deficiencies. Thirteen of the 22 patients had circulating immune complexes and 11/22 had milk precipitins. No patient had milk precipitins and a negative test for immune complexes. A serum sample drawn from a patient 60 min after he drank milk contained casein. The low level of immune complexes initially detected disappeared by 60 min and then reappeared, to

reach a max at 120 min. There were no significant changes in serum levels of total complement, C3, or C1q after the milk was consumed. It is possible that the complexed antigen in the circulations of these patients was a milk protein. (8 refs)

- 79-5241 Interferon in the Replication of Herpes Simplex Virus in Normal and Pathological Nerve Cells. (Eng) de la Pena, N. C. (Res. Dept. Inst. Oncology Angel H. Roffo, Buenos Aires Univ., Buenos Aires, Argentina); Bal, E.; Puricelli, L.; Diaz, A.; De Lustig, E. S. *IARC Sci Publ* 24(11): 1055-1066; 1978.

The role of human interferon (HI) and human colostrum secretory IgA (S-IgA) in herpes simplex virus (HSV) replication in the nervous system was studied in vitro. When trigeminal ganglia explants from rabbits with experimental herpetic keratitis were infected with HSV type 1 (HSV-1) and treated topically with HI or HI/S-IgA, HSV was recovered from 30% of the ganglia after 15-19 days cocultivation on rabbit kidney (RK 13) cells. A restrictive HSV productive infection was demonstrated in ganglia and nerves of newborn rabbits in organ culture, the yields always being higher in nerve cultures. HI had no direct effect on HSV-1 replication. However, when explants were treated with HI and IgG for 48 hr before and after infection, a delay in the expression of HSV-1 was detected by cocultivation. HSV-1 and HSV-2 replicated in a C1300 murine neuroblastoma clone, the cytopathic effects being more marked for HSV-2 at 24 hr. HSV-specific antigens were demonstrated by the immunoperoxidase technique. (11 refs)

- 79-5242 Carcinoembryonic Antigen (CEA) and CEA-like Activity in Ascites and Pleural Effusions. (Ger) Eimermacher, H. (Medizinische Universitätsklinik, Ruhruniversität Bochum, D-4630 Bochum, W. Germany); Tinnefeld, W.; Pressler, H.; Schuster, P.; Beyer, H. K. *Klin Wochenschr* 57(11): 575-579; 1979.

Carcinoembryonic antigen (CEA) levels were studied in nonmalignant ascites and pleural effusions from 18 patients with cardiac insufficiency pneumonia or liver cirrhosis and in malignant effusions from 21 patients with renal cell carcinoma or tumors of the liver, lungs, breast, stomach, uterine cervix, ovaries, and esophagus. Increased CEA activity (>2.5 nanograms/ml) was found in 1/18 benign effusions and in 12/21 malignant effusions. The correlation between CEA levels in serum and effusions was studied in 20 tumor patients: the serum CEA titers were elevated in 9/12 patients with elevated effusion titers and were normal in the 3 others. The serum CEA titer was also increased in 1/8 patients with a normal CEA effusion titer. The considerable discrepancy between the CEA levels in

the sera and effusions of the tumor patients shows that the tumor antigens are actively secreted by the tumor cells rather than simply released from the blood. (18 refs)

- 79-5243 Expression of "Ia-like" Antigens on Cells from a Human Endometrial Carcinoma Cell Line, END-1. (Eng) Carrel, S. (Unit Human Cancer Immunology, Lausanne Branch, Ludwig Inst. Cancer Res., 1066 Epalinges, s/Lausanne, Switzerland); Gross, N.; Heumann, D.; Mach, J. P. *Transplantation* 27(6): 431-433; 1979.

Evidence is presented that cells from a long-term human endometrial carcinoma cell line, END-1, express immune-associated (Ia)-like antigens, as assessed by complement-dependent lysis and by immunofluorescence using rabbit antiserum against Ia-like antigens. The presence of the antigens on the END-1 cells was confirmed by immunochemical demonstration of 28,000- and 33,000-mol wt components on the cell surface. (22 refs)

- 79-5244 Cell-mediated Cytotoxicity Engendered by IB-G-Region Determinants of the H-2 Complex. Absence of H-2K and D Restriction. (Eng) Wolf, S. J. (Immunobiology Res. Unit, Dept. Pathology, Univ. Pennsylvania Sch. Medicine, Philadelphia, PA); Elkins, W. L. *Immunogenetics* 8(2): 171-175; 1979.

The congeneric strains C57BL/10.A (4R) and (2R) differ in the central regions of the H-2 complex (IB-G segment). It is shown that one or more antigens encoded in the H-2 IB-G segment of the 2R genome stimulate 4R lymphocytes to give a strong cytotoxic response against P815 mastocytoma cell targets. The P815 tumor cells were obtained from the ascites fluid of serially transplanted DBA/2 mice. Single-cell suspensions provided 5×10^6 viable responder cells that were then cocultivated with 5×10^6 stimulator cells (previously inactivated by 2,500 R from a ^{137}Cs source). After incubation of the cultures for 5 days in humidified CO_2 at 37 C, killer cells were generated. Unstimulated or concanavalin A (Con A)-stimulated spleen cells provided the lymphoid target cells. The target cells were labeled with ^{51}Cr -sodium chromate. The results demonstrate that 4R anti-2R killers can be readily detected when P815 target cells are used. The killing of labeled P815 cells was inhibited equally well by unlabeled 2R lymphoblasts and P815. Since P815 and strain 2R share IC-G alleles derived from the H-2d chromosome, this genetic difference may be the source of the antigens recognized. The killing is not restricted by the H-2K or H-2D alleles, since P815 and strain 2R do not share these alleles. In one-third of the trials, the response to putative IC-G region antigens was approx as strong as that to H-2D antigens on the mastocytoma. (10 refs)

- 79-5245 Functional Separation In Vivo of Both Antigens Encoded by H-2 Subregion and Non-H-2 Loci. (Eng) Wolters, E. A. (Dept. Cell Biology and Genetics, Erasmus Univ., P.O. Box 1738, Rotterdam, Netherlands); Benner, R. *Nature* 279(5714): 642-643; 1979.

A delayed-type hypersensitivity (DHT) assay was developed to measure the occurrence of T-effector cells after in vivo immunization with different histocompatibility antigens. The DTH T-effector cells generated in graft vs host (GvH) and host vs graft reactions are specific for largely different sets of histocompatibility antigens, with selective stimulation by H-2I- and I-locus antigens under GvH conditions. (15 refs)

- 79-5246 Source of Tumor Cells Influences Their Immune Recognition by H-2-matched Mice. (Eng) Forni, G. (Inst. Microbiology, Univ. Torino, Via Santena 9, 10126 Turin, Italy); Varesio, L.; Giovarelli, M.; Landolfo, S. *Transplantation* 27(6): 433-435; 1979.

The presence of an appropriate WBC population enhanced the immune recognition of proliferating tumor cells in H-2 matched hosts, and it brought about the rejection of an otherwise lethal inoculum. DBA/2 mice challenged with ADK-1t adenocarcinoma cells of BALB/c origin (spontaneous) recognized minor alloantigens displayed by the tumor cells, but the immune reaction was not enough to block tumor proliferation. When inactivated BALB/c macrophages or B lymphocytes were mixed with the tumor cells, the tumor was rejected. (19 refs)

- 79-5247 HLA Compatibility in Couples with Children Suffering from Acute Leukemia or Aplastic Anemia. (Eng) Werner-Favre, C. (Transplantation Immunology Unit, Hopital Cantonal, 1211 Geneva 4, Switzerland); Jeannet, M. *Tissue Antigens Histocompat Immunogenet* 13(4): 307-309; 1979.

The frequency of common HLA-A and -B antigens was determined in 30 couples with a child with acute leukemia (AL), 34 couples with a child with aplastic anemia (AA), and 58 random couples with healthy children. The number of couples sharing at least two common antigens was increased among parents of children with AL and AA (30% and 26%, respectively, vs 8% of the couples with healthy children). (8 refs)

- 79-5248 Absence of Four H-2d Antigenic Specificities in an H-2d Sarcoma. (Eng) Garrido, F. (Tumour Immunology Unit, Facultad de Medicina,

Granada, Spain); Perez, M.; Torres, M. D. *J Immunogenet* 6(2): 83-86; 1979.

A BALB/c sarcoma, MCG4, induced as a solid tumor with 0.2 mg of methylcholanthrene, was serially transplanted sc in syngeneic mice. The ascites form obtained was used to study the expression of H-2 antigenic specificities in a postlabeling radioassay. MCG4 did not express H-2D.4 (private specificity of H-2d haplotypes) or H-2.3, H-2.8, and H-2.13 (public specificities). However, it did express H-2.5 (a public specificity not present in H-2d cells). These results were confirmed by quantitative absorption analysis using MCG4 and positive-negative normal lymphoid cells for a particular specificity. The expression of H-2 antigens may be controlled by regulatory genes. (14 refs)

- 79-5249 Possible Association Between HLA-AW24 and Metastatic Testicular Germ-Cell Tumours (Letter to Editor). (Eng) Carr, B. I. (Wisconsin Clinical Cancer Center, Madison, WI 53706); Bach, F. H. *Lancet* 1(8130): 1346-1347; 1979.

The possible association between HLA-A locus A antigen W24 and testicular germ-cell tumors was studied in 20 patients with testicular teratocarcinoma (9 with distant metastases). A total of 5/20 (25%) patients possessed the AW-24 antigen; all five had distant metastases (55%). The frequency of AW-24 in patients with metastatic tumors is significantly higher than the normal frequency (16%) in North American Whites ($P = 0.0075$) and than the frequency in the non-metastatic group ($P = 0.008$). It is suggested that the presence of the AW-24 antigen might indicate an increased likelihood of distant metastases in patients with non-seminomatous testicular germ-cell tumors. (13 refs)

- 79-5250 DNA-synthesizing T and Non-T Cells in Chronic Lymphocytic Leukemia. (Eng) van der Woerd-de Lange, J. A. (I. Medizinische Abteilung, Städtisches Krankenhaus Schwabing, Kolner Platz 1, D-8000 München 40, W. Germany); Dohrmann, J.; Huber, C.; Schick, P.; Rauert, K.; Begemann, H. *Blut* 37(6): 319-326; 1978.

In an effort to correlate the extent of blood lymphocyte proliferation with clinical parameters of underlying lymphoproliferative disease, the number of DNA-synthesizing peripheral blood lymphocytes in 21 patients with chronic lymphocytic leukemia (CLL) and in 8 hematologically normal persons was investigated autoradiographically. The lymphocytes were separated according to ability to form erythrocyte (E) rosettes into T and non-T lymphoid cells. There was a normal number of proliferating T lymphoid cells and an increased number of proliferating non-T lymphoid cells in clinical Stages 0-I. In Stages III-IV, there was a significant increase in the proliferation of both T and

non-T lymphoid cells. The data are compatible with, but do not prove, the view that blood lymphocyte proliferation in CLL is primarily a feature of the leukemic cells and that it correlates with the actual rate of production of the malignant cell clone. (20 refs)

- 79-5251 **Crawling Movements of Lymphocytes on and Beneath Fibroblasts in Culture.** (Eng) Chang, T. W. (Dept. Biology, Massachusetts Inst. Technology, Cambridge, MA 02139); Celis, E.; Eisen, H. N.; Solomon, F. *Proc Natl Acad Sci USA* 76(6): 2917-2921; 1979.

An approach to the analysis of the exploratory and migratory behavior of lymphocytes is described. Mouse lymphocytes were stimulated immunologically in vivo or in vitro. When introduced into a culture of mouse 3T3 or L cells (fibroblasts) and followed by live-cell microscopy, some of these lymphocytes were observed (without a time-lapse device) to crawl on top of, along the edges of, and preferentially beneath the attached fibroblasts. The crawling rate was as rapid as 20 $\mu\text{m}/\text{min}$. The ability of the lymphocytes to penetrate beneath attached 3T3 cells (diagnostic of crawling activity) was examined under a variety of conditions. Crawling was inhibited almost completely by decreasing the incubation temperature from 37 to 20-25 C, partially by treating the cells with 10 mM NaN_3 , and completely by exposing the cells to cytochalasin B (10 $\mu\text{g}/\text{ml}$) or colchicine (50 μM). These agents or treatments either interrupt energy metabolism or disrupt the cytoskeleton. Crawling was partially inhibited by removing both Ca^{2+} and Mg^{2+} but not by removing Ca^{2+} alone. Crawling lymphocytes were virtually absent in normal thymus and spleen cells, but they were greatly increased in 5-day mixed lymphocyte cultures and in peritoneal exudate lymphocytes taken after mice had been immunized with allogeneic tumor cells. T cells accounted for most of the crawlers in the mixed lymphocyte cultures. Of two T-cell leukemia lines tested, R1+ cells were crawlers but EL-4 cells were not. The H-2 haplotype of the 3T3 fibroblasts (ie, syngeneic or allogeneic) had no apparent effect on lymphocyte crawling activity. It is suggested that the crawling behavior may be related to immune surveillance (the exploration of cell-surface antigens by lymphocytes), to the mode of action of cytotoxic T cells, to the migration of lymphocytes across blood vessel walls, or to the penetration of lymphocytes into solid masses of normal or tumor tissue. (20 refs)

- 79-5252 **Lymphocytes Subpopulation in Normal Family Members of Patients with Alpha-Chain Disease.** (Eng) Alsabti, E. A. (Flat No. 5, 8 Norfolk Terrace, Brighton BN1 3AD, England); Safo, M. H.; Shaheen, A. *J Surg Oncol* 11(4): 365-374; 1979.

Sera from normal family members of eight patients with alpha-chain disease and intestinal lymphoma were in-

vestigated by immunoelectrophoresis for abnormal alpha-chain proteins. Abnormal proteins were detected in 23 members of four families; all the positive cases were first-degree relatives. In these relatives and the lymphoma patients, the proportion of circulating B lymphocytes was much higher than normal and that of T lymphocytes was lower than normal. Surface immunofluorescence studies indicated that the percentage of IgA-bearing lymphocytes was increased in the patients and their relatives with abnormal alpha-chain patterns. Serum IgA levels were also above normal in the patients and their relatives. Neither the patients nor the relatives could be sensitized to dinitrochlorobenzene, and their tuberculin skin tests were negative. These results suggest that alpha-chain disease is a B-cell disease of the IgA type and that it is transmitted by a hereditary factor associated with depressed cellular immunity. (17 refs)

- 79-5253 **Level of 3-Oxyanthranilic Acid in the Urine of Patients with Urinary Bladder Cancer.** (Rus) Korosteleva, T. A. (Lab. Immunology Carcinogenesis, N. N. Petrov Res. Inst. Oncology, Leningrad, USSR); Kliucharev, B. V.; Benteleva, T. A. *Vopr Onkol* 25(6): 36-39; 1979.

An immunological assay was developed to detect an antigen containing as a determinant 3-oxyanthranilic acid (3-OAA), in the urine of patients with urinary bladder cancer. Urine specimens from 38 patients (20 had papillary tumors and 18 had infiltrative tumors of the urinary bladder) were assayed in a double-diffusion reaction with rabbit antisera containing antibodies against 3-OAA. The antigen was present in 25/38 patient urine specimens, but it was absent from the urine of all 17 healthy controls. (8 refs)

- 79-5254 **Reduced Lymphocyte Stimulation as an Expression of Reduced Immunoreactivity in Cancer Patients.** (Ger) Heilmann, E. (Medizinischen Poliklinik der Westfälischen Wilhelms-Universität Münster, Münster, W. Germany); Sasse, W.; Berghaus, I. *Inn Med* 6(3): 94-98; 1979.

Mitogen stimulation of cultured peripheral blood lymphocytes from 87 cancer patients and 45 healthy controls was compared. All patients had undergone surgery 6-12 mo previously; none were given cytostatics, radiotherapy, or corticosteroids, except for 20 with breast carcinoma, who had finished radiotherapy >6 mo previously. The effects of pokeweed mitogen (PWM, 100 $\mu\text{g}/\text{ml}$), phytohemagglutinin (PHA, 0.5 $\mu\text{g}/\text{ml}$), concanavalin A (Con A, 100 $\mu\text{g}/\text{ml}$), and lipopolysaccharide (LPS, 50 $\mu\text{g}/\text{ml}$) were studied by measuring ^3H -thymidine (TdR) uptake after 72 hr of incubation with mitogen only and after 10 hr of incubation with TdR. After stimulation with PHA, PWM, or

Con A, the av TdR uptake was less than one-half of the control value for cells from 60 patients with gastrointestinal carcinoma and 20 women with breast carcinoma ($p < 0.01$). Uptake was higher in cells from all categories of patients after stimulation with LPS. In seven patients who had carcinoma of the papilla of Vater, uptake after the other three mitogens was similar to that of controls. Except for the breast cancer patients, the av uptake of the patients cells was higher ($p < 0.05$) than that of control cells if no mitogen was added. The unstimulated uptake of cells from breast cancer patients was close to the control value. The clinical significance of lymphocyte stimulation by mitogens cannot be ascertained without further study. (23 refs)

- 79-5255 Blastogenic Response of Spleen Cells from C1300 Neuroblastoma-bearing Mice to Tumor Cells or Soluble and Insoluble Tumor Antigens. (Eng) Sugimoto, T. (Dept. Pediatrics, Kyoto Prefectural Univ. Medicine, Hirokoji Kawaramachi, Kamigyo-ku, Kyoto 602, Japan); Sawada, T.; Tozawa, M.; Kusunoki, T.; Kishida, T. *Gann* 70(3): 327-336; 1979.

The blastogenic (BG) response of spleen cells from C1300 neuroblastoma-bearing A/J mice to tumor cells or soluble and insoluble tumor antigens was studied. Mice inoculated with 1×10^6 syngeneic neuroblastoma cells had a palpable tumor after 1 wk, and the tumor grew uniformly. A hypertonic KCl extract of the tumor induced a BC response in syngeneic spleen cells from tumor-bearing mice, and the tumor antigens were considered solubilized from the tumor cells by KCl. Soluble tumor antigens and insoluble tumor antigens attached to Sepharose 4B beads induced equal spleen cell BG activity. The BG activity of spleen cells to insoluble tumor antigens was less than one-third of that in the mixed lymphocyte-tumor cell reaction (MLTR) assays. The initial information of the BG response was transmitted to the responder cells without the entrance of tumor antigens into the cells, as shown by experiments using insoluble tumor antigens. BG responses to soluble tumor antigens and to irradiated tumor cells (MLTR) in spleen cells from tumor-bearing mice were serially assayed after tumor cell injection. The response to soluble tumor antigens reached a peak 2 wk after inoculation, but a progressive depression of the response was observed after marked tumor growth. Although the BG activity of soluble tumor antigens was small, changes in consecutive responses to soluble tumor antigens in tumor-bearing mice were well-correlated with those in the MLTR. The BG responses to soluble tumor antigens and MLTR were considered to be the manifestation of tumor-specific cell-mediated immunity. Furthermore, the serial BG responses to concanavalin A and lipopolysaccharide were also coincident with those of tumor-specific immunity. (27 refs)

- 79-5256 Effect of ALS or ATS Administration on Tumor Formation in Two-Stage Skin Carcinogenesis. (Eng) Stenback, F. (Dept. Pathology, Univ. Kuopio, Harjulantie 1, Kuopio, Finland); Curtis, G.; Ryan, W. *Cancer Immunol Immunother* 6(2): 125-128; 1979.

The effects of antilymphocyte serum (ALS) and antithymocyte serum (ATS) on two-stage skin carcinogenesis were determined in female Swiss mice. The mice were given a single dose of 9,10-dimethylbenz(a)anthracene (DMBA: 50 μ g) followed by twice weekly applications of 12-O-tetradecanoylphorbol-13-acetate (TPA) for 25 wk. Some of the mice were also given four injections of ALS or ATS (1.25 mg/100 g/injection) during initiation or promotion. When given during initiation, ATS increased the tumor incidence by 83%, increased the number of tumors/animal from 2.6 to 4.2, and decreased the latent period by 27%, compared with animals given DMBA/TPA alone. ATS had a less-pronounced effect when given during promotion: tumor incidence was increased by 50%, and the av number of tumors per animal was 3.1. When given during initiation, ALS increased the tumor incidence by 33%, and the av number of tumors/animal was 3.1. When ALS was given during promotion, the effect on tumor formation was negligible; ie, 52 tumors were observed in 21 animals, vs 48 tumors in 18 DMBA/TPA-treated animals. The types of tumors formed, their biological behavior, and their morphology were not markedly affected by ALS or ATS. Almost all tumors were benign papillomas. The results show an obvious enhancing effect of immunosuppressive treatment. ATS and, to a certain degree, ALS, may allow a larger number of potential neoplastic foci to grow and become manifest as visible tumors. During promotion, only a small number of latent cells are affected, causing a less obvious increase in tumor incidence. (26 refs)

- 79-5257 Pinocytic Activity and CSF Production of Macrophages During the Growth of the Lewis Lung Carcinoma in Mice. (Eng) Von Melchner, H. (Westdeutsches Tumorzentrum, Innere Universitätsklinik (Tumorforschung), Hufelandstr. 55, D-4300 Essen 1, W. Germany); Hilgard, P. *Eur J Cancer* 15(5): 779-783; 1979.

^{198}Au colloidal gold was used to record the pinocytic activity of peritoneal macrophages from C57BL mice bearing transplanted Lewis lung carcinomas. Although macrophage uptake of gold particles was depressed 3 days after tumor transplantation, nonspecific stimulation by thioglycolate increased their pinocytic activity above that of control macrophages. Ten days posttransplantation, macrophage gold uptake was still suppressed and the response to stimulation decreased. During the final stage of tumor growth (day 16), the macrophages appeared to be activated spontaneously since no additional uptake was

recorded after thioglycolate injection. An increase in blood clearance and splenic uptake of gold particles by tumor-bearing animals on days 13 and 16 correlated with the in vitro finding of macrophage stimulation during the final stage of tumor growth. The depression of pinocytic activity on day 10 was associated with a decrease in the production of macrophage colony-stimulating factor. (10 refs)

- 79-5258 Phospholipid Methylation in Macrophages Is Inhibited by Chemotactic Factors. (Eng) Pike, M. C. (Lab. Immune Effector Function, Howard Hughes Medical Inst., Duke Univ. Medical Center, Durham, NC 27710); Kredich, N. M.; Snyderman, R. *Proc Natl Acad Sci USA* 76(6): 2922-2926; 1979.

In an attempt to define the methylation requirement for chemotaxis, the effect of chemotactic factors (CF's) on protein carboxy-O-methylation and phospholipid (PL) methylation in male Hartley guinea pig macrophages was examined. Chemotactic agents tested over a wide dose and time range produced no alteration in carboxy-O-methylation. However, these agents did produce an effect on the methylation of phosphatidylethanolamine (PE) by macrophages. S-adenosyl-L-methionine-mediated PL methylation was inhibited by as much as 73% by CF's, and there was excellent correlation ($r = 0.99$) between their concentrations for producing half-max chemotactic responses and for inhibiting PL methylation. The inhibition of methylation by CF's was observed at all incubation times and could not be explained by an increased turnover of membrane PL. Neither the chemotaxis antagonist fPhe-Met nor the nonchemotactic tripeptide Met-Met-Met significantly depressed PL methylation. Immune phagocytosis by macrophages similarly did not alter PL methylation. The CF's produced no alteration in total macrophage PL synthesis or in PL methylation in a non-chemotactic cell type. The formation of newly methylated derivatives of PE in macrophages was decreased by a biologically active dose of CF. These findings indicate that CF's are capable of altering the methylation of PE in chemotactically responsive cells. The inhibition of PL methylation by CF's may be necessary for the translation of a chemotactic signal on the surface of the cell into directional cell movement. (20 refs)

- 79-5259 Rat Mutant (*nznu*) Showing "Nude" Characteristics. (Eng) Berridge, M. V. (Wellington Cancer and Medical Res. Inst., Clinical Sch. Medicine, Wellington, New Zealand); O'Kech, N.; McNeilage, L. J.; Heslop, B. F.; Moore, R. *Transplantation* 27(6): 410-413; 1979.

A new rat mutant (*nznu*) that shows characteristics similar to those of the nude mouse is described. The discovery of hairless rats in a colony of outbred albinos led to the

establishment of a conventionally maintained colony in which there is a predictable incidence of nude rats. The mutant is an autosomal recessive trait. The homozygotes are essentially hairless (except for stunted vibrissae) and they show deficient thymus gland development. Under conventional breeding conditions, the mutants are difficult to raise and few survive weaning. The absence of functional thymus-derived lymphocytes in the nude rat is implied by (1) an acceptance of histoincompatible skin grafts, (2) a lack of response to the T-cell mitogens phytohemagglutinin and concanavalin A, and (3) an absence of cells sensitive to alloantiserum directed against rat thymus-derived lymphocytes. Although total blood WBC from the nude rat were within the normal range, differential counting of WBC showed a 4-fold elevation of neutrophils and a 2.5-fold reduction of lymphocytes, compared with levels in normal rats. Phenotypically normal heterozygotes gave values intermediate between those of nude and normal rats. (17 refs)

- 79-5260 Spontaneous Tumors in Nude Mice: Effect of the Viable Yellow Gene. (Eng) Stutman, O. (Memorial Sloan-Kettering Cancer Center, New York, NY 10021). *Exp Cell Biol* 47(2): 129-135; 1979.

The incidence and type of spontaneous tumors in athymic nude (*nu/nu*) mice (partially inbred in a CBA/H background) that were also carrying the viable yellow gene (*A-vy*, derived from C57BL/6JA-*vy* mice) were comparable to those observed in the phenotypically normal *nu/+* and *+/+* control crosses carrying the *A-vy* gene. The *A-vy* gene increased the incidence of spontaneous and induced tumors in most mouse strains. These results argue against a role of thymus-dependent immunity as a possible control mechanism of tumor development. (23 refs)

- 79-5261 Cellular Tumorigenicity in Nude Mice: Test of Associations among Loss of Cell-Surface Fibronectin, Anchorage Independence, and Tumor-forming Ability. (Eng) Kahn, P. (Dept. Genetics, Albert Einstein Coll. Medicine, Bronx, New York 10461); Shin, S. *J Cell Biol* 82(1): 1-16; 1979.

Fibronectin (FN; also called large external transformation-sensitive protein or cell-surface protein), a glycoprotein that is frequently absent or greatly reduced on the surface of malignant cells grown in vitro, may be a useful marker of cellular malignancy. Therefore, tests of the specific association among the degree of expression of FN, anchorage-independent cell growth, and tumorigenicity in athymic nude mice were carried out in a variety of diploid cell strains and established cell lines. When the presence of surface FN was assayed by indirect immunofluorescence using rabbit antisera against human cold insoluble globulin, rodent plasma FN, or chicken cell-surface FN,

tumorigenic cells often showed very low surface fluorescence although many highly tumorigenic fibroblast cell lines from several species stained strongly with all three antisera. Nontumorigenic cell lines almost always exhibited an extensive extracellular matrix of FN. When cells were assayed for the ability to form colonies in methylcellulose, anchorage-dependent and FN-positive phenotypes cosegregated and were the uniform phenotype in nontumorigenic cells, with the exception of three anchorage-independent human skin fibroblast lines, two of which were FN-positive and one FN-negative. While anchorage-independent and FN-negative phenotypes usually cosegregated in tumorigenic cells, they occasionally dissociated; and usually it was the anchorage-independent rather than FN-negative phenotype that cosegregated with tumorigenicity. When FN-positive but anchorage-independent cells were grown as tumors in nude mice and then reintroduced into culture, five of the six tumor-derived cell lines retained the same amount of surface FN. Hybrids between normal human diploid fibroblasts and the highly malignant mouse cell line A9 were mostly anchorage-independent, FN-positive, and tumorigenic in nude mice. These results indicate that the loss of cell-surface FN is not a necessary step in the process of malignant transformation and that the growth of FN-positive cells as tumors does not require a prior selection *in vivo* for FN-negative subpopulations. (65 refs)

- 79-5262** Immunochemical Characterization of Surface Antigens of TerC, a Teratocarcinoma-derived Cell Line. (Eng) Larraga, V. (Instituto de Immunologia y Biologia Microbiana, Velazquez 144, Madrid-6, Spain); Edidin, M. *Proc Natl Acad Sci USA* 76(6): 2912-2916; 1979.

Additional information on the biochemical characterization of antigens precipitated from surface-labeled TerC cells (derived from the mouse testicular teratoma 402AX) and from cross-reacting cl Id cells (derived from mouse L cells). Rabbit and mouse antisera prepared against 402AX cells precipitated both glycoproteins and glycolipids from detergent extracts of ¹²⁵I-labeled TerC cells. Extracts of immunoprecipitates with chloroform/methanol (2:1, (volume/volume)) were resolved on thin-layer gels into multiple peaks. More species were seen in extracts of TerC cells than in extracts of the cross-reacting cl Id cells. The teratocarcinoma antigens could be extracted out of chloroform/methanol into buffered saline. Incubation in these secondary extracts converted unreactive cells (lymphocytes) to cells reactive with antisera against the teratocarcinoma. Furthermore, the coated cells absorbed at least 80% of the activity of antisera against TerC target cells. (28 refs)

- 79-5263** Cell Surface Antigens of Human Melanoma Identified by Monoclonal Antibody. (Eng)

Yeh, M. Y. (Div. Tumor Immunology, Fred Hutchinson Cancer Res. Center, Seattle, WA 98104); Hellstrom, I.; Brown, J. P.; Warner, G. A.; Hansen, J. A.; Hellstrom, K. E. *Proc Natl Acad Sci USA* 76(6): 2927-2931; 1979.

Mouse NS-1 myeloma cells were fused with spleen cells from BALB/c mice that had been immunized with a short-term explant of a human melanoma (M1804). Hybrid cells were grown in selective medium and tested for the production of antibody to surface antigens of M1804 cells. Three hybrids produced antibodies that bound to the melanoma cells but not to autologous skin fibroblasts, and these hybrids were cloned. Antibodies produced by two of the clones were cytotoxic to M1804 cells in the presence of rabbit complement. Extensive specificity tests showed that the antibodies produced by the clones bound strongly only to M1804 cells; significant, although weaker, binding occurred with 2/11 allogeneic melanomas. Apart from weak binding of the antibody produced by one of the clones to a breast carcinoma, binding assays of 5 carcinomas, 1 sarcoma, and fibroblasts from 17 individuals were negative, as were cytotoxic tests of 10 lymphoblastoid cell lines and peripheral blood lymphocytes from 68 normal donors and 12 chronic lymphocytic leukemia patients. These results suggest that one or more determinants of a melanoma-associated antigen(s) whose expression is limited to a small proportion of melanomas were identified. (16 refs)

- 79-5264** Clonal Evolution of Myeloma Cells Leads to Quantitative Changes in Immunoglobulin Secretion and Surface Antigen Expression. (Eng) Lcibson, P. J. (La Rabida-Univ. Chicago Inst., Chicago, IL 60649); Loken, M. R.; Panem, S.; Schreiber, H. *Proc Natl Acad Sci USA* 76(6): 2937-2941; 1979.

The evolution of variants from a single well-differentiated myeloma cell was studied. A fresh clonal isolate of S107 myeloma cells possessing large amounts of surface IgA was continuously passaged *in vitro* for 2 yr. During this period, fluorescence-activated cell sorter analysis indicated the development of subpopulations possessing decreased amounts of surface IgA. Cells from these variant subpopulations were isolated by first using the cell sorter to enrich for cells with decreased amounts of surface IgA and then cloning the selected population in soft agar. The 50 sublines that were isolated showed heritable differences in their levels of surface IgA and H-2 antigens and in their rates of myeloma protein secretion. Sublines having either large amounts, intermediate amounts, or an absence of surface IgA also had corresponding large amounts, intermediate amounts, or an absence of myeloma protein secretion. In contrast, a decrease or loss of surface immunoglobulin did not correlate with decrease or loss of viral envelope glycoprotein gp71 and H-2 antigens. The variants did not resemble the phenotypes of less-differentiated normal lymphocyte populations of the B-cell lineage. The isolation and characterization of these

variants allow the mechanisms and pathways of tumor cell differentiation to be studied along with the regulation and function of cell-surface proteins. (36 refs)

- 79-5265 Amino Acid Sequence of a Mouse Immunoglobulin μ Chain. (Eng) Kehry, M. (Div. Biology, California Inst. Technology, Pasadena, CA 91125); Sibley, C.; Fuhrman, J.; Schilling, J.; Hood, L. E. *Proc Natl Acad Sci USA* 76(6): 2932-2936; 1979.

The amino acid sequence of the secreted μ chain derived from the BALB/c mouse myeloma tumor MOPC 104E is reported. The $C\mu$ region contains four consecutive homology regions of approx 110 residues and a COOH-terminal region of 19 residues. A comparison of this μ chain with a complete μ chain sequence from human (Ou) and a partial μ chain sequence from dog (Moo) revealed a striking gradient of increasing homology from the NH_2 -terminal to the COOH-terminal portion of these μ chains, with the former being the least and the latter the most highly conserved. Four of the five sites of carbohydrate attachment appeared to be at identical residue positions when the constant regions of the mouse and human μ chains were compared. The μ chain of MOPC 104E has a carbohydrate moiety attached in the second hypervariable region. This is particularly interesting in view of the fact that MOPC 104E binds α -(1-3)-dextran, a simple carbohydrate. The structure of the secreted μ chain places several constraints on the membrane-bound μ chain of the IgM receptor molecule. (44 refs)

- 79-5266 Progressive Hypogammaglobulinaemia in a Child Born to a Mother with Hodgkin's Disease. (Eng) Evans, D. I. (Royal Manchester Children's Hosp., Pendlebury, Manchester M27 1HA, England); Burn, J. L. *Arch Dis Child* 54(4): 313-315; 1979.

A 29-yr-old woman developed Hodgkin's disease (nodular sclerosis) in the third trimester of pregnancy and gave birth to a boy who developed common variable immunodeficiency. Initially, the boy's IgG levels were normal, his IgA and IgM levels were low, and he had an antibody deficiency. IgG levels fell progressively over 4 yr. Cellular immunity was normal. It is suggested that this is a further family with immune deficiency presenting with common variable immunodeficiency and lymphoid malignancy. The father and an elder child were normal. (7 refs)

- 79-5267 Family Studies in Acute Leukemia in Childhood: A Possible Association with Autoimmune Disease. (Eng) Till, M. (Dept. Haematology, Inst. Child Health and Hosp. Sick Children, Great Ormond St., London WC1N 3JH, England); Rapson, N.; Smith, P. G. *Br J Cancer* 40(1): 62-71; 1979.

Medical histories of themselves and their first-degree relatives were obtained from the parents of 82 leukemic children [54 acute lymphoblastic (ALL), 28 acute myeloblastic (AML)] and from control couples matched for age. The possibility of primary familial immunological abnormality as an etiological factor in childhood leukemia was suggested by the fact that some infections were reported significantly more frequently by the parents than by the controls. This possibility was supported by the finding of a significantly ($P < 0.02$) increased prevalence of autoimmune disorders (eg, rheumatic fever and thyroid disorders associated with thyrotoxicosis or myxedema) among the ALL families, compared with the controls. No significant differences were found for other conditions such as peptic ulcer, infectious hepatitis, tuberculosis, or malignant disease. An analogy is drawn between these families and Down's syndrome and NZB mice, in which diminished T-cell function is associated with autoimmune disease and lymphoid neoplasia. Varicella and herpes zoster occurred, respectively, in 2 ALL mothers during their pregnancies involving the patients. This supports previous evidence that antenatal varicella infections may be an etiological factor in some cases of ALL. (17 refs)

- 79-5268 B-Cell Lymphoma Lacking Fc- and C3d-Receptors. (Eng) Thiel, E. (Abteilung Immunologie, Instituts für Hamatologie, GSF München, Landwehrstrasse 61, D-8000 Munich 2, W. Germany). *Blut* 37(6): 307-312; 1978.

Various cell-surface markers were studied in the lymphocytes from a 61-yr-old man with lymphosarcoma cell leukemia. Immunofluorescence and immunoradiography tests of the surface immunoglobulins (SIg) of the patient's lymphocytes revealed the monoclonal expression of IgM-type SIg of high density. This finding confirmed the B-cell origin of the leukemia. Interestingly, no Fc or C3d receptors could be demonstrated by various techniques. Only 22% of the leukemic cells expressed C3b receptors. The failure of the lymphocytes to form rosettes with mouse RBC was an additional surface feature that distinguished this disorder from ordinary B-cell type chronic lymphatic leukemia. The phenotype of the leukemia cells corresponded to that of less-differentiated B lymphocytes. (23 refs)

- 79-5269 Premature Multiple Bowen's Disease in Poikiloderma Congenitale with Warty Hyperkeratoses. (Eng) Haneke, E. (Dermatologische Universitätsklinik, Hartmannstrasse 14, D-8520 Erlangen, W. Germany); Gutschmidt, E. *Dermatologica* 158(5): 384-388; 1979.

A gradual malignant degeneration of verrucous hyperkeratoses was observed in a young girl with poikiloderma congenitale (PC) and cellular immune defi-

ciency. Although topical immunotherapy with dinitrochlorobenzene, initiated at age 14, resulted in the disappearance of numerous hyperkeratoses and in partial restoration of T-cell functions (eg, phytohemagglutinin lymphocyte stimulation index), the warty lesions recurred at age 15 and 16. Histological examination confirmed their transformation to highly malignant Bowen's lesions. The immune deficiency in this PC patient was also associated with impaired WBC function and reduction of B lymphocytes in the peripheral blood. (12 refs)

- 79-5270 A Serologically Detected Tumour-specific Membrane Antigen of Murine Lymphomas Which Is Not the Target for Syngeneic Graft Rejection. (Eng) Davey, G. C. (Div. Tumor Immunology, Chester Beatty Res. Inst., Belmont, Sutton, Surrey, England); Currie, G. A.; Alexander, P. *Br J Cancer* 40(1): 168-170; 1979.

Experiments demonstrating the presence, in the membrane of murine (DBA/2) lymphomas, of a tumor-specific cross-reacting antigen that does not act as a target for graft rejection are presented. Mice were injected ip with 10^7 previously irradiated (5,000 rads) lymphoma cells (SL/2, (L5178Y/E or L5178Y/ES) on day 0 and challenged ip with live cells on day 7 (10^3 to 10^5 cells). L5178Y/ES was less immunogenic than L5178Y/E, and there was no cross-protection between them; SL/2 was of intermediate immunogenicity and showed no cross-protection with L5178Y/E. An antiserum to SL/2 was raised in allogeneic mice with cells pretreated with anti-DBA/2 serum. The antiserum was initially toxic to both normal and malignant DBA/2 tissues, but after three absorptions on packed DBA/2 cells for 1-2 hr at 4 C, the antiserum had no toxicity for normal DBA/2 spleen cells, lymph node cells, or thymocytes or for two non-DBA/2 lymphomas, TLX-9 and TLC-5. However it was still highly cytotoxic in the presence of complement for SL/2, L5778Y/E, and L5178Y/ES. These data suggest that the antiserum recognizes a tumor-specific membrane component common to the three DBA/2 lymphomas. (6 refs)

- 79-5271 Heterotransplantation of Human Basal Cell Carcinomas in "Nude" Mice. (Eng) Pawlowski, A. (Clinical Science Div., Univ. Toronto, Medical Sciences Bldg., Room 7318, Toronto M4S 1A8, Canada); Haberman, H. F. *J Invest Dermatol* 72(6): 310-313; 1979.

The heterotransplantation of basal cell carcinomas (BCC's) from 10 human patients into 25 nude mice by grafting and sc inoculation was studied. BCC's developed in 2/12 mice given tumor grafts and in 3/13 mice inoculated sc. In the two mice with grafted tumors, typical islands of closely

packed tumor cells were visible in the dermis, whereas tumor cells in the animals with sc implants did not form these characteristic islands. Union between human and mouse epidermis was observed in two mice with grafted BCC's and in three other mice in which BCC's were not identified. Of the 20 mice in which the tumor did not take, complete necrosis of the implant was observed in 7, an inflammatory infiltrate appeared in the skin of 5, and increased skin vasculature and innervation was observed in 6. Seventy days after transplantation and 2 wk after the disappearance of the inoculum, one mouse developed a lymphoblastic/lymphocytic lymphoma. Immunological, vascular, stromal, and other environmental factors may have accounted for the low percentage of tumor takes. (17 refs)

- 79-5272 Vasculitis and Sjogren's Syndrome with IgA-IgG Cryoglobulinemia Terminating in Immunoblastic Sarcoma. (Eng) Aizawa, Y. (Dept. Internal Medicine, Keio Univ., 35 Shinanomachi, Shinjuku-Ku, Tokyo, Japan); Zawadzki, Z. A.; Micoloughi, T. S.; McDowell, J. W.; Neiman, R. S. *Am J Med* 67(1): 160-166; 1979.

Clinical, immunochemical, and pathologic findings in a 68-yr-old woman with a 12-yr history of systemic vasculitis and arthralgia who developed generalized lymphadenopathy and other manifestations of Sjogren's syndrome are reported. An unusual immunologic feature was hypogammaglobulinemia and IgA monoclonal immunoglobulinemia with mixed IgA-IgG cryoglobulin. At autopsy, the histopathologic findings were compatible with immunoblastic sarcoma. The monoclonal IgA protein, found in serum and the pleural and pericardial fluids, showed rheumatoid factor activity. Immunocytes from the immunoblastic sarcoma were found to be the source of the monoclonal IgA protein. (17 refs)

- 79-5273 Immunosuppression by a Mouse Tumor Resembles Antigenic Competition. (Eng) Cocito, C. G. (Dept. Microbiology and Genetics, Inst. Cell Pathology, Univ. Louvain, Medical Sch., Brussels, Belgium); Michot, B.; Radovich, J.; Talmage, D. W. *Proc Natl Acad Sci USA* 76(6): 2895-2897; 1979.

The ip injection of γ -irradiated, UV-irradiated or unirradiated P-185 tumor cells into syngeneic (DBA2) or allogeneic (C3H) mice suppressed the immune response to a subsequent ip injection of sheep RBC in a manner similar to the suppression caused by the injection of horse RBC and termed antigenic competition. In both cases, the greatest suppression occurred when the sheep RBC were injected at the same site (ip) as the tumor antigen and in a dose of 10^8 RBC or less. (10 refs)

- 79-5274 Suppression of Naturally Occurring Antitissue Antibodies During Growth and after Removal of Tumours. (Eng) Chandradasa, K. D. (Dept. Immunology, Univ. Liverpool, P.O. Box 147, Liverpool L69 3BX, England); Elson, C. J. *Gann* 70(3): 261-266; 1979.

The level and type of circulating antitumor antibodies were examined during tumor growth and during the induction of tumor immunity in inbred Wistar rats. The sera of normal rats were active in the complement fixation test against isogenic tumor homogenates. This activity was heat-labile, and it sedimented with IgM globulins upon zone ultracentrifugation in sucrose density gradients. Sera from rats bearing progressively growing tumors and sera from rats that had their tumors excised were less active than normal rat sera in the complement fixation test against isogenic tumor and liver homogenates. This suppression of naturally occurring antitissue antibodies may be a specific process related to the host immune response to the tumor. (33 refs)

- 79-5275 Low Natural-Killer-Cell Activity in Familial Melanoma Patients and their Relatives. (Eng) Hersey, P. (Kanematsu Memorial Inst., Medical Res. Dept., Sydney Hosp., Macquarie St., Sydney, New South Wales 2000, Australia); Edwards, A.; Honeyman, E. M.; McCarthy, W. H. *Br J Cancer* 40(1): 113-122; 1979.

Fifteen melanoma patients who had one or more close relatives with melanoma were studied for their natural killer cell (NK) activity against cultured melanoma cells and Chang cells. A high proportion of the patients and their relatives had low NK activity against these target cells. In most of the patients, this response could not be attributed to general depression of their immune function, since B- and T-cell numbers and the mitogenic response to phytohemagglutinin were within normal limits. The levels of NK activity of the patients and their relatives were found to be significantly correlated, suggesting that the NK activity in these families may have been genetically (or environmentally) determined. Several genetic markers were examined in the patients and their relatives for association with the disease state and NK activity. No association with histocompatibility (HLA) antigens or ABO blood groups were detected, but there was a low incidence of the Rhesus-negative phenotype in the patients (the Rh phenotype had previously been associated with high NK activity). The results indicate that NK activity has a familial association in families with a high incidence of melanoma, and they raise the question whether low NK activity may be one of the predisposing factors in the development of familial melanoma. (15 refs)

- 79-5276 AU Cell-Surface Antigen of Human Malignant Melanoma: Solubilization and Partial Characterization. (Eng) Carey, T. E. (Dept. Otorhinolaryngology, KHRI, Univ. Michigan Medical Center, Rm. 6020, 1301 E. Ann St., Ann Arbor, MI 48109); Lloyd, K. O.; Takahashi, T.; Travassos, L. R.; Old, L. J. *Proc Natl Acad Sci USA* 76(6): 2898-2902; 1979.

Antibody-inhibition tests were used to follow the solubilization and partial characterization of AU antigen, a unique tumor antigen restricted to the cell surface of melanoma cells from one patient (AU). The AU melanoma cell line is designated SK-MEL-28. Limited papain digestion (4-10 units/ml used with $5 \cdot 10^7$ cells/ml at 37 C for 30 min) was found to solubilize AU antigen along with B₂-microglobulin (B₂m) and histocompatibility locus antigen (HLA) allogeneic and xenogeneic specificities. Comparable papain treatment of other melanoma and nonmelanoma cell lines solubilized B₂m and HLA but not AU antigen. The max yield of AU antigen occurred after short (5-15 min) digestion times, whereas longer digestion times (up to 90 min) were required to maximize B₂m and HLA release. AU antigen was not immunoprecipitated by rabbit antiserum against B₂m or HLA under conditions leading to partial or complete removal of B₂m or HLA, showing that molecules with AU reactivity do not carry B₂m or HLA determinants. After affinity chromatography fractionation on a *Lens culinaris* hemagglutinin-agarose column, the specific activity of AU antigen was 30-50 times greater in the mannoside-eluted pooled fraction, indicating that molecules with AU determinants are glycoproteins, at least in part. When a papain digest of SK-MEL-28 cells was fractionated on a Sephadex G-150 column, about one-third of the AU activity eluted in the void volume of the column, and the major peak of AU activity eluted after the major protein peak in the mol wt range of 20,000-50,000 daltons. (13 refs)

- 79-5277 Psoriasis and Cancer (2 Letters to Editor). (Eng) Polani, P. E. (Pediatric Res. Unit, Guy's Hosp. Medical Sch., London SE1 9RT, England); Shuster, S.; Chapman, P. H.; Rawlins, M. D. *Br Med J* 1(6172): 1215; 1979.

The relation of psoriasis to histocompatibility antigen (HLA) haplotypes would be of interest in determining why, as determined in a previous study, psoriatics appear to be relatively resistant to cancer. Impaired aryl hydrocarbon hydroxylase (AHH) activity in psoriatic skin was also noted. The authors of the study reply that recent HLA analyses of psoriasis patients with decreased epidermal AHH activity showed that they had an increased frequency of BW17 antigens. (5 refs)

- 79-5278 Variations in the Level of Haematogenous Antitumor Immunity During Progressive Tumour Growth and Spontaneous Blood-borne Metastatic Spread. (Eng) Proctor, J. W. (Div. Radiation Oncology, Allegheny General Hosp., 320 E. North Ave., Pittsburgh, PA 15212); Mastromatteo, W. P.; Antos, M.; Hedderson, E. D. *Oncology* 36(2): 49-54; 1979.

Inbred DBA₂ mice bearing the syngeneic 1699 mammary tumor in their hind limb were challenged iv with ¹²⁵I-iododeoxyuridine-labeled single 1699 cell suspensions, and the amount of radioactivity in the lungs was compared 20-24 hr later with that in the lungs of normal mice or in those of mice bearing the antigenically unrelated syngeneic SaD₂ tumor. An immunologically specific decrease in radioactivity was evident at various times after tumor induction, depending on the number of cells used to induce the leg tumors, but the radioactivity fell below that in normal mice as the leg tumors progressed beyond a wt of approx 1 g. As assessed by microscopic scanning of serial histological sections of the same lungs, the incidence of spontaneous metastases rose to between 80% and 100% immediately after the amount of cell loss from the lungs of the tumor-bearing mice returned to that of the normal controls. This extremely rapid series of events does not allow a definitive conclusion as to whether immunity failed and led to metastatic spread or vice versa, but it does underline the strong association of immunity with the blood-borne dissemination of tumor cells in this tumor system. Following excision of the tumors, in no instance was immunity detected 14 days later, and, in a single experiment, it did not reach detectable limits until 25 days after excision, a time when the incidence of lung metastases fell to 14% as a result of spontaneous regression. (23 refs)

- 79-5279 Structure of Tumor Antigen on Hybrid Cells Between Mouse Mammary Ascites Tumor and Mouse Fibroblast L Cells. (Eng) Kubota, K. (The Wistar Inst. Anatomy and Biology, 36th St. at Spruce, Philadelphia, PA 19104). *Int J Cancer* 24(1): 114-120; 1979.

Somatic cell hybrids between mouse fibroblast L cells and MM2 mouse mammary ascites tumor cells grown in BALB/c mice were isolated, and the structures of the tumor-associated surface antigens (TASA's) of the hybrid cells and the parental cells were investigated by radioiodination of membrane proteins, immunoprecipitation with a specific antiserum against the TASA's of MM2 tumor (anti-MM2 serum), and sodium dodecyl sulfate-polyacrylamide gel electrophoresis. Two molecules of 105,000 daltons (105K) and 76K were detected on the MM2 cell surface, but no MM2 tumor antigen was detected on the mouse L cells. On the hybrids, molecules of 48K-51K and 12K were observed in addition to the two MM2 tumor antigens. On Sendai virus-infected mouse L cells, only a 68K molecule was detected by the anti-MM2 serum. This

molecule was also detected by normal mouse serum, which indicates that antibodies against Sendai virus were present in both the anti-MM2 and normal mouse sera used and that the molecules detected on the hybrid cells were distinguishable from possible viral components of Sendai virus on the hybrid cells. Thus, the somatic cell hybrids expressed on their surface the molecules that were not expressed on either parent cell. The newly detected molecules had an electrophoretic pattern that was similar to that of H-2 antigen. (20 refs)

- 79-5280 A New Experimental Model of Human Cachexia. (Eng) Strain, A. J. (Ludwig Inst. Cancer Res., Royal Marsden Hosp., Sutton, Surrey SM2 5PX, England); Easty, G. C.; Neville, A. M. *Invest Cell Pathol* 2(2): 87-96; 1979.

A renal cell carcinoma removed from a man who had lost 30 kg in the 2 mo preceding surgery was grown as a nonmetastasizing transplantable xenograft in immune-suppressed female CBA/lac mice. The tumor produced a considerable wt loss (>25%) in the mice at a stage when it comprised <5% of the total body wt. A slight fall in food intake of the tumor-bearing mice was noted, but animals bearing other noncachectic mouse and human tumors had much lower food intakes without accompanying wt loss. No obvious defects in gastrointestinal absorption were detected, nor was any gross increase in the basal metabolic rate observed. The precise mechanism producing the severe cachexia remains to be established, but elaboration of humoral factors by the tumor seems probable. This model of cachexia bears a closer relation to the clinical situation than do other experimental animal tumor models currently available. (27 refs)

- 79-5281 Multiple Primary Tumors in Patients with Urological Tumors: Reduced Immunocompetence? (Ger) Klippel, K. F. (Urologische Klinik, Johannes-Gutenberg-Universität, Langenbeckstrasse 1, D-6500 Mainz, W. Germany); Hutschenreiter, G.; Jacobi, G.; Graff, J. *Onkologie* 2(1): 12-16; 1979.

The immune status of 55 patients with multiple primary malignant tumors, including at least one urological tumor, and of control patients with solitary tumors was studied by determining immunoglobulin levels, B- and T-cell counts, and the response of lymphocytes to stimulation and by the dinitrochlorobenzene skin test. The average age of the 55 patients was 58.1 yr at the manifestation of the first tumor and 64.3 yr at the manifestation of the second tumor. The male:female ratio was 4:1. The first tumors included hypernephromas, carcinomas of the bladder, prostate,

IMMUNOLOGY

penis, testicles, colon, uterine cervix, vagina, lungs, larynx, pharynx, salivary glands, ovaries, and tongue, and myeloproliferative neoplasms. The second tumors included carcinomas of the prostate, lungs, anus, uterus, urinary bladder, colon, urethra, and renal pelvis; hypernephromas; malignant teratomas; hepatocellular carcinomas; rhabdomyosarcomas; and seminomas. The immunological tests failed to show any significant differences in immune status between the patients with double tumors and the control patients with solitary tumors, but they revealed that both groups had a diminished immunocompetence compared with another control group of patients with nonmalignant diseases. PATHOGENESIS

- 79-5282 Cell Interactions in the Differentiation of a Melanotic Tumor in *Drosophila*. (Eng) Rizki, R. M. (Div. Biological Sciences, Univ. Michigan, Ann Arbor, MI 48109); Rizki, T. M. *Differentiation* 12(3): 167-178; 1979.

The cellular events in the formation of melanotic tumors in the tumor-W (*tu-W*) mutant larva of *Drosophila melanogaster* were studied. The first step was transition of spherical plasmocytes into flattened, disk-like variants called lamellocytes. This morphologic transition was accompanied by extrusion of intracellular fluids. Melanotic tumor formation was limited to the caudal region of the larval fat body. Globular and membranous materials appeared at the intercellular boundaries of the adipose cells, and the hemocytes actively engulfed materials oozing from the surfaces of these cells. The basement membrane of the caudal fat body underwent dissolution and lamellocytes and hemocytes in transition to the lamellocytic form landed on the adipose cell surfaces which lacked basement membrane. Layering of hemocyte upon hemocyte continued until a laminated capsular wall surrounded the entire area of adipose cells. Regions between apposing lamellocytes were traversed by electron dense fibrillary material which extended into the cytoplasm of adjacent cells. Small vesicles originating from the surfaces of the hemocytes were observed. They tended to adhere to the hemocyte surface and were trapped between the lamellocytes. It is suggested that the vesicles play a role in lamellocyte-to-lamellocyte adhesion during the initial stages of hemocyte aggregation at the tumor site. (15 refs)

- 79-5283 Genetic Associations of Transitional Cell Carcinoma. (Eng) Herring, D. W. (Dept. Surgery, Dryburn Hosp., Durham, England); Cartwright, R. A.; Williams, D. D. *Br J Urol* 51(2): 73-77; 1979.

A series of 101 cases of transitional cell carcinoma (TCC) was contrasted with a control series for several genetic parameters. The three genetic associations demonstrated in the TCC patients were ABO A, HLA B5 and HLA CW4 gene frequencies higher than expected. Classification of the natural history of the disease showed that HLA frequencies vary with the severity of the disease. (16 refs)

- 79-5284 Autopsy Case of Histiocytic Medullary Reticulosis in an Infant. (Jpn) Oku, T. (Se-

cond Dept. Pathology, Yamaguchi Univ. Sch. Medicine, Ube, Yamaguchi Prefecture 755, Japan); Sasai, K.; Ogino, T.; Tani, S.; Takahashi, M. *Gan No Rinsho* 25(6): 644-647; 1979.

A 20-mo-old boy presented with hepatosplenomegaly, anemia, and a tendency to hemorrhage. Peripheral blood levels of erythroblasts and monocytes were suggestive of erythroleukemia or monocytic leukemia; Letterer-Siwe disease was also considered because of the many atypical histiocytes in the bone marrow. The child died 23 days after admission due to severe intestinal bleeding. A diagnosis of histiocytic medullary reticulosis was established on the basis of autopsy findings. The bleeding was ascribed to histiocytic infiltration of the intestinal mucosa. (25 refs)

- 79-5285 Invasion of Malignant C3H Mouse Fibroblasts from Aggregates Transplanted into the Auricles of Syngenic Mice. (Eng) Meyvisch, C. (Dept. Experimental Cancerology, Clinic for Radiotherapy and Nuclear Medicine, Academic Hosp., De Pintelaan 135, B 9000 Ghent, Belgium); Mareel, M. *Virchows Arch [Cell Pathol]* 30(1): 113-122; 1979.

Spheroid aggregates of malignant fibroblasts (MO₄ cells), which are invasive in vitro and in vivo, were implanted sc into the auricles of syngeneic female inbred C3H/HeA mice to study early stages of invasion. Animals were killed 6 hr-30 days after inoculation, and the auricles were studied in serial sections. After 6 hr, a few MO₄ cells showed cytoplasmic extensions in contact with connective tissue or with muscle cells. Polymorphonuclear WBC (PMN's), mainly neutrophils, (PMN's) were present in the outer part of the MO₄ aggregate. After 24 hr, the MO₄ aggregates contained macrophages and lymphocytes as well as PMN's. Many MO₄ cells at the periphery of the aggregate had assumed a stretched configuration. After 2 days, MO₄ cells were further away from the aggregate, suggesting progressive invasion. Newly formed blood vessels were observed in the vicinity of the aggregate. In most auricles fixed after 4 days, no MO₄ cells were found at the site of the original aggregate. Proliferative foci in auricles inoculated with an MO₄-aggregate differed from control auricles in their higher cell density and their lower collagen content. Palpable tumors were present after 20-30 days; they showed the histological characteristics of fibrosarcomas. It is concluded that a small number of invasive MO₄ cells will grow into a palpable tumor at a site where there is a favorable microenvironment. (26 refs)

- 79-5286 Expression of Malignancy in Hybrids Between Normal and Malignant Cells. (Eng) Croce, C. M. (Wistar Inst. Anatomy and Biology, 36th St. at Spruce, Philadelphia, PA 19104); Barrick, J.; Linnenbach, A.; Koprowski, H. *J Cell Physiol* 99(3): 279-286; 1979.

Somatic cell hybrids between normal human fibroblasts, phenotypically normal mouse fibroblasts, or mouse peritoneal macrophages and HT1080 human diploid fibrosarcoma cells were studied for their ability to form tumors in BALB/c nude mice. Hybrids between normal and malignant human cells were tumorigenic, and there was no consistent pattern of reduction or increase in the number of chromosomes or any specific human chromosome pair. Nontumorigenic hybrids between D98 hypoxanthine phosphoribosyltransferase-deficient human carcinoma cells and normal human diploid fibroblasts were fused with cells from a patient with β -glucuronidase deficiency. Only 1/4 of the hybrid lines was tumorigenic in nude mice; the tumors were positive for glucose-6-phosphate dehydrogenase types A and B. Hybrids between phenotypically normal mouse cells and HT1080 cells were tumorigenic, indicating that the normal mouse genome is incapable of suppressing malignancy. Hybrids between HT1080 cells and mouse peritoneal macrophages were also tumorigenic, indicating that the presence of mouse chromosome 4 does not result in the suppression of malignancy. The data indicate that tumorigenic behavior is expressed as a dominant trait in both human-human and mouse-human hybrid cells. (21 refs)

- 79-5287 Inflammatory Oncotaxis (Letter to Editor). (Eng) DerHagopian, R. P. (Univ. Miami Sch. Medicine, Miami, FL). *JAMA* 241(21): 2264; 1979.

The possibility of the occurrence of malignant tumors in old sites of inflammation such as scars is discussed. The capillaries in these loci have been shown to end blindly. These dead-end capillaries may act as easy entrapment points for circulating malignant cells. (2 refs)

- 79-5288 Macrocytic Anemia, Thrombocytosis and Nonlobulated Megakaryocytes. The 5q-Syndrome, a Distinct Entity. (Eng) Mahmood, T. (Denver Veterans Admin. Medical Center, 1055 Clermont St., Denver, CO 80220); Robinson, W. A.; Hamstra, R. D.; Wallner, S. F. *Am J Med* 66(6): 946-950; 1979.

The clinical, hematologic, and histologic characteristics of six patients (5 women, 1 man, aged 42-79 yr) with refractory anemia showing deletion of the long arm of chromosome 5 are described. These patients had a distinct hematologic picture: macrocytic anemia of mild to moderate severity, a normal to low WBC count, and an increased platelet count. The long arm of chromosome 5 was

deleted in most of the bone marrow metaphases. The main cause of anemia was underproduction with decreased erythroid precursors in the bone marrow and no increase in peripheral blood reticulocytes. Two of five patients responded transiently to the administration of androgens. The bone marrow growth pattern in semisolid agar was evaluated for three patients, and it was found to be normal and distinct from that of patients with preleukemia. In a follow-up of up to 5 yr, no patient had changed hematologically and in none had leukemia developed. The 5q syndrome is a distinct hematologic entity and is probably more common than previously realized. This diagnosis may have prognostic implications. (20 refs)

- 79-5289 Acute Leukemia and Preleukemia in Eight Males in a Family: An X-linked Disorder? (Eng) Li, F. P. (44 Binney St., Boston, MA 02115); Marchetto, D. J.; Vawter, G. F. *Am J Hematol* 6(1): 61-69; 1979.

The occurrence of acute leukemia or potentially preleukemic conditions in eight male members of a French-Canadian family is reported. The affected members were descendants of a single man: two grandsons and a great-grandson resulting from his first marriage; and two sons, two grandsons, and a great-grandson resulting from his second marriage. In seven patients, the underlying clinical disorder appeared to be acute leukemia that followed a period of pancytopenia. Aplastic anemia was initially diagnosed in 3/7, and three additional patients had histories of bone marrow hypoplasia and peripheral cytopenias; the seventh patient had typical acute lymphocytic leukemia. Light-chain disease in the eighth patient was distinct from preleukemia, but it is another hematologic disease in which acute leukemia tends to develop. An X-linked inheritance of the fatal hematologic disorders was suggested, although this mechanism required that the two wives of the proband be carriers of the same rare disease. (27 refs)

- 79-5290 Familial Lymphoproliferative Malignancy: Clinical and Laboratory Follow-up. (Eng) Blattner, W. A. (NCI, NIH, Bethesda, MD 20014); Dean, J. H.; Fraumeni, J. F. *Ann Intern Med* 90(6): 943-944; 1979.

The occurrence of B-cell neoplasms and immune defects among descendants and surviving first-degree relatives of three siblings (2 brothers, cases 11-1 and 11-6, and a sister, case 11-10) with chronic lymphocytic leukemia (CLL) is reported. The daughter of 11-6 developed a poorly differentiated lymphocytic lymphoma, another brother developed a squamous cell carcinoma of the lung, and a granddaughter of 11-6 developed a well-differentiated squamous cell carcinoma in her thigh. Persistent immune defects in

several members of this family link the predisposition to B-cell neoplasms to an inherited defect in immune regulation. The immune defects took various forms, usually impaired responses to phytohemagglutinin, immunoglobulin abnormalities, and depressed stimulation in mixed WBC culture. No clear relationship was found between the HLA haplotype of II-6 (HLA-A2, B15, CW3, and DW1) and the immune dysfunction in the family. However, because this haplotype was shared by the family members with a lymphoproliferative malignancy, susceptibility may be related to a major histocompatibility-associated gene. (10 refs)

- 79-5291 **The Preleukemic Syndrome. Correlation of In Vitro Parameters of Granulopoiesis with Clinical Features.** (Eng) Greenberg, P. L. (Veterans Admin. Hosp., 3801 Miranda Ave., Palo Alto, CA 94304); Mara, B. *Am J Med* 66(6): 951-958; 1979.

To determine the clinical utility of in vitro marrow culture techniques for evaluating the preleukemic syndrome, in vitro parameters of granulopoiesis were correlated with the clinical courses of 43 prospectively studied patients with the syndrome. The clinical features of these cytopenic patients with a marrow morphology showing hemopoietic dysplasia included the following: median age, 61 yr; combined cytopenias, 60%; low WBC alkaline phosphatase, 67%; splenomegaly, 33%; median survival, 18.9 mo; and 2-yr actuarial probability of survival, 55%. Transformation into acute myeloid leukemia occurred in 19 patients within a median period of 19.1 mo. Presenting pancytopenia was the only clinical feature indicative of subsequent acute transformation, with 69% of the patients undergoing such an evolution within a median period of 15 mo. Lethal infections were frequent during the preleukemic period. Abnormalities of in vitro marrow myeloid clonal growth were initially present in 72% of the patients showing significantly low granulocyte-monocyte colony-forming cell (CFU-GM) values and a high proportion of light-density CFU-GM. Persisting or progressive decrements in CFU-GM values sequentially occurred prior to or concomitant with acute transformation in six patients. Markedly diminished initial CFU-GM values (≤ 2 colonies/ 10^5 marrow cells) were predictive for a significantly decreased (19%) 2-yr probability of survival ($p < 0.004$), whereas no clinical feature showed this association. Marrow cell and urinary colony-stimulating activity output were normal during the chronic phase of the disorder. These in vitro myeloid culture studies are useful adjuncts to marrow morphology and clinical features for diagnostic and prognostic characterization of patients with this syndrome. (29 refs)

- 79-5292 **Contribution of Cytogenetics to the Study of Hemopathies.** (Fre) Cadotte, M. (Service de Cytogenetique, Hotel-Dieu de Montreal, Montreal, Canada). *Union Med Can* 108(5): 511-514; 1979.

The value of cytogenetic studies in the diagnosis of hemopathies is illustrated in two cases. In one case, detection of the Philadelphia chromosome permitted the diagnosis of leukemic infiltration vs a diagnosis of lymphoma. In a patient with polycythemia vera, leukemia was diagnosed after detection of the Philadelphia chromosome. (4 refs)

- 79-5293 **Subacute Myeloid Leukemia. A Clinical Review.** (Eng) Cohen, J. R. (Suite 202, 2410 Samaritan Drive, San Jose, CA 95124); Creger, W. P.; Greenberg, P. L.; Schrier, S. L. *Am J Med* 66(6): 959-966; 1979.

Data on 31 patients (22 men and 9 women aged 17-86 yr) who fit into the clinical spectrum of subacute myeloid leukemia were reviewed. Most patients were men with a median age of 61 yr. The interval from onset of symptoms to actual diagnosis was extremely variable, with a mean of 16 mo and a median of 6 mo. Most patients presented with anemia and thrombocytopenia, although the WBC count varied from striking leukopenia to marked leukocytosis. Examination of the bone marrow invariably revealed abnormalities of all cell lines with megaloblastoid erythropoiesis and dysplastic megakaryocytopoiesis. Although the white cell line showed a prominence of immature forms, there was more maturation than is seen in acute myeloid leukemia. Survival from diagnosis was variable, from < 1 mo to > 68 mo, with a median of only 6 mo. Anemia and hepatosplenomegaly were prognosticators of a poor outlook; patients with hepatosplenomegaly in association with either leukocytosis or thrombocytopenia had a particularly poor outlook, with a median survival of only 1.5 mo. Approx half the patients received chemotherapy with no demonstrated effect on survival. (27 refs)

- 79-5294 **Pathophysiology of Lymphocyte Transformation. A Study of So-called Composite Lymphomas.** (Eng) van den Tweel, J. G. (Dept. Pathology, Hematopathology Section, Univ. Southern California Sch. Medicine, Los Angeles, CA 90033); Lukes, R. J.; Taylor, C. R. *Am J Clin Pathol* 71(5): 509-520; 1979.

The occurrence of two different histologic types of lymphoma in one organ, in two different organs at the same time, or during the course of the disease is an intriguing biologic phenomenon. An immunohistologic study was made of 10 such cases, 7 consisting of two different non-Hodgkin's lymphomas (NHL's) and 3 in which Hodgkin's disease (HD) was one of the components. The findings in the NHL group are in keeping with emerging immunologic and physiologic concepts; ie, the different component parts appear to represent different maturation stages of the

neoplastic B lymphocyte. In the cases in which HD and a NHL were observed, there was a surprising similarity between the malignant cells of both tumors when they were studied by immunoperoxidase techniques for anti-light-chain and anti-heavy-chain antibodies. These observations may serve to resurrect an old belief in the common origin of certain of the NHL's and, possibly, of HD. It is concluded that true composite lymphomas are extremely rare and that most of the cases described as such in the literature are, in reality, different morphologic expressions of a single malignant cell type, the lymphocyte. (33 refs)

- 79-5295 HLA Antigens in Familial Hodgkin's Disease. (Eng) Greene, M. H. (Environmental Epidemiology Branch, NCI, Landow Building, Room 3C-07, Bethesda, MD 20205); McKeen, E. A.; Li, F. P.; Blattner, W. A.; Fraumeni, J. F. *Int J Cancer* 23(6): 777-780; 1979.

The histocompatibility locus (HLA) antigen distribution in 19 men and 12 women with Hodgkin's disease from 13 multiple case families was studied. Of the 13 probands (so designated before testing), 7 had the Bw35 antigen; less than 2 were expected on the basis of the frequency of this antigen in the general population ($p = 0.01$). This antigen was present in 14/23 patients evaluated, all of the positive patients being between 15 and 44 yr old (median, 23 yr). There was no association between Bw35 and histologic subtype. In three families, Aw24 was linked with Bw35, and all but one patient in these families shared the haplotype 24-35. All three patients in one of these three families also carried the Cw4 antigen. Antigen Bw37 also occurred more frequently than expected in the 31 patients (3 observed, 0.5 expected, $p = 0.03$). No significant antigen deficits were observed. These results suggest that immunogenetic mechanisms account at least in part for the familial predisposition to Hodgkin's disease. (28 refs)

- 79-5296 Differential Counts of Neutrophil, Eosinophil, and Macrophage Colonies in Cultures from Human Bone Marrow and Peripheral Blood. (Eng) Nissen-Druey, C. (Abteilung Hamatologie, Medizinische Universitätsklinik, Kantonsspital Basel, Petersgraben 8, CH-4000 Basel, Switzerland); Speck, B. *Blut* 37(5): 241-248; 1978.

Neutrophil, eosinophil, and macrophage colonies were counted in cultures of bone marrow and peripheral blood from 246 patients with a variety of diseases and 80 normal controls. Eosinophil and macrophage colonies were increased in patients with carcinomas, Hodgkin's disease, lymphoma with bone marrow involvement, graft-vs-host disease, myeloma, and acute myelogenous leukemia in remission. They were virtually absent in cultures from the peripheral blood of patients with chronic granulocytic

leukemia and myelofibrosis, and they were reduced in patients with nonmalignant leukopenias. Normal peripheral blood cultures had a higher proportion of eosinophil colonies than normal bone marrow cultures but a lower proportion of macrophage colonies. It is concluded that in vitro conditions favor eosinophil commitment. As a nonspecific sign of disease, increased commitment is therefore more likely to be recognized in vitro than in vivo. (5 refs)

- 79-5297 Histiocytic Lymphoma in a Patient with Lennert's Lymphoma: Report of a Case with Unusual Cytoplasmic Inclusions. (Eng) Miller, R. (Dept. Pathology, Medical Univ. South Carolina, 171 Ashley Ave., Charleston, SC 29403); Spicer, S. S.; Kurtz, S. M. *Arch Pathol Lab Med* 103(6): 279-283; 1979.

A case of Lennert's lymphoma followed by histiocytic lymphoma is presented. The patient, a 55-yr-old woman who presented with lower left quadrant abdominal pain, wt loss, and a palpable mass in the epigastric region, also suffered from Lennert's lymphoma diagnosed 3 yr earlier. Exploratory laparotomy revealed grossly enlarged lymph nodes in the mesenteric and para-aortic regions. The pathologic diagnosis was diffuse histiocytic lymphoma. Electron microscope examination demonstrated that many of the histiocytic lymphoma cells possessed a well-demarcated paranuclear accumulation of fine filaments. The filamentous inclusions contained free ribonucleoprotein particles and coated vesicles interspersed between the filaments. The inclusions stained strongly for IgG and less strongly for K and γ light chains. Immunostaining for IgA showed occasional cells with diffuse and paranuclear globular staining. No IgM was detected. The positive polyclonal staining of the paranuclear inclusions suggested aberrant immunoprotein production and indicated that the neoplasm was of B cell origin. (29 refs)

- 79-5298 Infiltrating Pituitary Neoplasms in the Rat. (Eng) Magnusson, G. (Dept. Pathology, Huntingdon Res. Centre, Huntingdon, PE18 6ES, England); Majeed, S. K.; Gopinath, C. *Lab Anim* 13(2): 111-113; 1979.

Spontaneous pituitary neoplasms occurred in 442/1,371 male and 596/1,238 female CFY Sprague-Dawley outbred specific-pathogen-free rats. In all but two males and nine females, the neoplasms were diagnosed as pituitary adenomas arising from the anterior lobe. In the other 11 rats, the pituitary tumors infiltrated the adjacent brain tissue. (9 refs)

- 79-5299 Medullary Carcinoma of the Thyroid: A Clinicopathologic and Ultrastructural Study in

a Patient with Sipple's Syndrome. (Eng) Clark, M. A. (Dept. Lab. Medicine, Div. Anatomic Pathology, Natl. Naval Medical Center, Bethesda, MD 20014); Lack, E. E.; Kramer, S. N. *Milit Med* 144(6): 381-384; 1979.

A case of Sipple's syndrome associated with medullary carcinoma of the thyroid (MCT) occurred in a 34-yr-old woman. Chemical evidence of hyperparathyroidism was detected prior to confirmation of elevated calcitonin levels. Ultrastructural studies of the MCT showed that there were two predominant cellular elements corresponding to light and dark cells, plus some intermediate forms. (12 refs)

79-5300 Incidental Medullary Thyroid Carcinoma in Sporadic Hyperparathyroidism. An Expansion of the Concept of C-Cell Hyperplasia. (Eng) LiVolsi, V. A. (Dept. Pathology, Yale Univ. Sch. Medicine, 310 Cedar St., New Haven, CT 06510); Feind, C. R. *Am J Clin Pathol* 71(5): 595-599; 1979.

A 54-yr-old man and a 66-yr-old woman with sporadic primary hyperparathyroidism were found to harbor tiny medullary thyroid carcinomas. In addition, parafollicular cell hyperplasia was recognized in one of these thyroids by the use of an immunoperoxidase stain to localize calcitonin. Animal experiments support the theory that the hypercalcemia of parathyroid hormone excess evokes a calcitonin response from the parafollicular cells. The two patients appear to represent an extension of the concept of the progression of sporadic C-cell hyperplasia to neoplasia. It is concluded that the lesions in both had progressed to carcinoma, one of which metastasized. It is not believed that resolution of the hypercalcemic state by removal of the parathyroid adenoma could have reversed the neoplastic C-cell lesions. These two cases draw attention to the possible coexistence of true medullary thyroid cancer in patients with sporadic hyperparathyroidism. (27 refs)

79-5301 On the Natural History of Plummer's Disease. (Eng) Wiener, J. D. (Dept. Medicine, Academisch Ziekenhuis der VU, 1007 MB Amsterdam, Netherlands); de Vries, A. A. *Clin Nucl Med* 4(5): 181-190; 1979.

A series of 58 untreated patients with Plummer's disease (autonomous goiter) were re-examined on one or more occasions over periods of 1-12 yr. Gross clinical or scintigraphic changes were seen in 13 patients, minor changes in 14. However, the disease progressed rapidly in 2/300 other patients. Since low-grade malignancy has been reported in over 10% of the reported American cases of Plummer's disease, there may be more than a chance relationship between the two pathologies. In the absence of suspected thyrotoxic crises or malignancy, it is concluded that Plummer's disease may be left untreated. (31 refs)

79-5302 An Unusual Cause of Obstructive Jaundice. (Dut) Simonis, R. F. (Afdeling Inwendige Geneeskunde, Ziekenhuis Leyenburg, Leyweg 275, Hague, Netherlands); Smits, P. J.; Bender, J. *Tijdschr Gastroenterol* 21(3): 167-174; 1978.

A 69-yr-old man developed obstructive jaundice suggestive of pancreatic malignancy. A tumor found in the head of the pancreas proved to be a late metastasis of a renal cell carcinoma that had been removed by left nephrectomy 9 yr earlier. (15 refs)

79-5303 Severe Pancreatic Involvement in Three Generations in von Hippel-Lindau Disease. (Eng) Fishman, R. S. (Div. Gastroenterology and Internal Medicine, Mayo Clinic, Rochester, MN); Bartholomew, L. G. *Mayo Clin Proc* 54(5): 329-331; 1979.

Extensive pancreatic involvement in three patients with Von Hippel-Lindau disease (VHLD) is reported. The first patient was a 60-yr-old man who had at least six family members with tumors typical of VHLD. The other patients were the 20-yr-old daughter of this man and his mother, who was seen at age 39 yr. The first patient had a history of cerebellar hemangioendothelioma and a retinal angioma, an angiographically documented slow-growing vascular tumor involving the entire pancreas and many other abdominal organs, recent onset of insulin-dependent diabetes, and pronounced steatorrhea that responded to pancreatic extract. It was concluded that the abdominal tumor was part of the VHLD and that complete infiltration of the pancreas had led to exocrine and probably endocrine pancreatic insufficiency. There was no clinical or laboratory evidence to suggest small bowel or hepatic dysfunction. The other two patients had complete replacement of the pancreas by cysts but no overt pancreatic insufficiency. As of 1972, only 101 cases of visceral involvement in VHLD had been reported; the pancreas was affected in 24%. Benign cysts are the most common pancreatic lesions. (7 refs)

79-5304 Establishment and Characterization of a Human Neuroblastoma Cell Line in Tissue Culture. (Eng) Sekiguchi, M. (Dept. Clinical Oncology, Inst. Medical Science, Univ. Tokyo, Shirokanedai, Minato-ku, Tokyo 108, Japan); Oota, T.; Sakakibara, K.; Inui, N.; Fujii, G. *Jpn J Exp Med* 49(1): 67-83; 1979.

The characteristics of a new continuous human neuroblastoma line, GOTO, are described. The line was obtained from a tumor arising in the adrenal gland of a 13-mo-old male infant, and it has been maintained in tissue culture for 5 yr. The cells are small and fibroblastlike, and they grow in a dense layer. The population doubling time is approx 48 hr, and the modal chromosome number is near-

diploid. Neither marker chromosomes nor double minute chromosomes have been observed. Injection of 10^7 cells produced tumors in antithymocyte serum-treated hamsters and athymic nude mice, and the histological appearance of the tumors was consistent with that of an undifferentiated neuroblastoma. The neural features of the cells were also confirmed by ultrastructural examination. Biochemical analysis showed that this cell line is cholinergic. Morphological differentiation leading to neurite formation was induced by cultivation of the cells in serum-free medium. (50 refs)

- 79-5305 Peutz-Jeghers Syndrome. (Fre) Baillot, R. (Departement de Chirurgie, Hopital Maisonneuve-Rosemont, Montreal, PQ, Canada); Le Gresley, L. P.; Girard, R. M. *Can J Surg* 22(3): 207-211; 1979.

Peutz-Jeghers syndrome was diagnosed in a 17-yr-old boy and in a 21-yr-old woman. A recurrence of the polyps was seen in the boy 3 yr after polypectomy. An aunt and cousin of the woman with Peutz-Jeghers syndrome had mucocutaneous pigmentation, as did her child born 8 yr after she underwent surgery to remove esophageal polyps. (30 refs)

- 79-5306 Genetic Linkage Studies Between Congenital Adrenal Hyperplasia and the HLA Blood Group System. (Eng) Grosse-Wilde, H. (Institut für Med. Virologie und Immunologie, Universitätsklinikum Essen, Hufelandstrasse 55, D-4300 Essen 1, W. Germany); Weil, J.; Albert, E.; Scholz, S.; Bidlingmaier, F.; Sippel, W. G.; Knorr, D. *Immunogenetics* 8(1): 41-49; 1979.

The linkage between the histocompatibility (*HLA*) and the *C-21-hydroxylase* deficiency genes and its correlation with the results of a biochemical test for congenital adrenal hyperplasia (CAH) were studied. Seventeen families with one or two children suffering from CAH were not only typed for their *HLA-A*, *B*, and *D* antigens but also tested biochemically for CAH heterozygosity after ACTH stimulation. There was a close genetic linkage between CAH and *HLA*, indicating that the *C-21-hydroxylase* deficiency gene(s) causing CAH in the homozygous deficient state is located close to the *HLA* complex on chromosome 6, with an estimated recombination fraction of 0%-5%. *HLA* typing in 21 unrelated CAH patients revealed a statistically significant association with *HLA-B5* antigen, for a relative risk value of 5.8. There was a significant correlation ($p = 0.0025$) between the *HLA* segregation data and the CAH heterozygosity test results in relatives of CAH patients, although a few false-negative results in the CAH heterozygosity test were observed. Thus, the combination of *HLA* typing and this biochemical test currently

provides the most precise approach for detecting CAH carriers in families of CAH patients. (15 refs)

- 79-5307 Tumor Interaction with the Fibrinolytic System. (Eng) Malone, J. M. (Dept. Surgery, Arizona Health Sciences Center, Tucson, AZ 85724); Gervin, A. S.; Moore, W. S.; Keown, K. *J Surg Res* 26(5): 581-589; 1979.

Tumor interaction with the fibrinolytic system was evaluated, and the potential of tumor activation and inhibition of fibrinolysis as biologic markers for metastatic disease was studied. Normal tissue and tumor specimens were obtained from human patients. Most normal tissue demonstrated moderate amounts of fibrinolytic activity (200-600 mm^2), but no normal tissue other than liver demonstrated inhibition of fibrinolysis. All benign lesions showed significant activation of fibrinolysis but no inhibition of fibrinolysis. All malignant neoplasms, except two superficial spreading melanomas, demonstrated inhibition of fibrinolysis (33-312 mm^2). With the exception of embryonal cell carcinoma, all malignant neoplasms also demonstrated activation of fibrinolysis (12-1508 mm^2). Most malignant lesions without metastatic spread had fibrinolytic activity levels $<600 \text{ mm}^2$, whereas most tumors with metastatic spread had fibrinolytic activity levels $>600 \text{ mm}^2$. Nonmetastatic tumors had an av tumor activation/inhibition (A/I) ratio of 4.09; metastatic tumors had an av A/I ratio of 18.36. (32 refs)

- 79-5308 Familial Pheochromocytoma: A Report of 2 Cases in a Kindred. (Eng) Kaufman, J. J. (Dept. Surgery, Div. Urology, Univ. California Los Angeles Sch. Medicine, Los Angeles, CA); Franklin, S. *J Urol* 121(6): 801-804; 1979.

The sixth and seventh documented cases of pheochromocytoma in one family are reported. The proband, a 36-yr-old woman, had classical features of adrenal medullary hyperfunction in addition to Raynaud's phenomenon. After surgical removal of the right adrenal gland, which contained a pheochromocytoma and a small paraganglioma, the patient was free of symptoms. The 12-yr-old son of the proband was discovered to have relatively asymptomatic sustained hypertension on routine examination. Biochemical and radiological tests confirmed the diagnosis of a left adrenal pheochromocytoma. (14 refs)

- 79-5309 Hormone-mediated Watery Diarrhea in a Family with Multiple Endocrine Neoplasms. (Eng) Hutcheon, D. F. (Johns Hopkins Hosp., Baltimore, MD 21212); Bayless, T. M.; Cameron, J. L.; Baylin, S. B. *Ann Intern Med* 90(6): 932-934; 1979.

The case reports of a father (age 63) and son (age 30) with pancreatic islet cell tumors and long histories of severe watery diarrhea (7 and 4 yr duration, respectively) are presented. The son had a pancreatic islet cell tumor associated with the pancreatic cholera syndrome and a parathyroid adenoma. The father had multiple islet cell adenomas and the Zollinger-Ellison syndrome. Pancreatic tumor tissue from each patient contained detectable gastrin and vasoactive intestinal peptide; however, a much higher gastrin concentration was found in the tumor tissue from the father and a much higher vasoactive intestinal peptide content was found in the tumor tissue from the son. Thus, watery diarrhea may be mediated by different hormones in families having multiple endocrine neoplasia. The precise cause of the diarrheal syndrome should be defined to ensure the proper therapy. (14 refs)

- 79-5310 Intracranial Tumors with Psychiatric Symptoms. Report of Three Cases. (Dan) Schmidt, J. (Afdeling B, Psykiatrisk ved Aarhus, Baekkelundsvej 14, DK-8240 Risskov, Denmark). *Ugeskr Laeger* 141(20): 1330-1331; 1979.

Brain tumors were found in three men, aged 62, 47, and 45 yr, undergoing treatment in a psychiatric ward; the initial diagnosis was alcoholic dementia, reactive psychosis, and endogenous depression, respectively. The tumors were identified as a meningioma of the olfactory nerve, a malignant tumor of the left frontoparietal lobe, and a meningeal sarcoma of the left frontotemporal region. Periodical disturbances of consciousness were typical symptoms. (8 refs)

- 79-5311 Primary Intracranial Epidermoid Carcinoma. Case Report. (Eng) Nosaka, Y. (Dept. Neurosurgery, Okayama Univ. Medical Sch., 2-5-1 Shikata-cho, Okayama, Japan); Nagao, S.; Tabuchi, K.; Nishimoto, A. *J Neurosurg* 50(6): 830-833; 1979.

The case report of a 46-yr-old man with a primary intracranial epidermoid carcinoma that was detected by computerized tomography (CT) is presented. A CT scan demonstrated a lesion with faintly increased absorption in the right cerebellopontine angle. Postcontrast CT revealed two discrete areas of homogeneous enhancement. Microscopically, the tumor consisted of a large amount of desquamated keratinized material lined by squamous cell carcinoma. At autopsy, the tumor was found to have invaded the brain stem, in spite of the absence of widespread leptomeningeal infiltration. (10 refs)

- 79-5312 Localized Primary Intracranial Ewing's Sarcoma of the Orbital Roof. Case Report. (Eng)

Alvarez-Berdecia, A. (Section Neurological Surgery, Univ. Puerto Rico, GPO Box 5067, San Juan, Puerto Rico 00936); Schut, L.; Bruce, D. A. *J Neurosurg* 50(6): 811-813; 1979.

A rare case of primary Ewing's sarcoma arising from the intracranial portion of the right orbital roof occurred in a 6-yr-old boy. The patient presented with two rapidly growing tender lumps on his forehead and a 1-yr history of headaches. X-rays showed marked diastasis of the coronal suture and a mottled appearance on the right frontal bone suggestive of sarcoma. Computerized tomography revealed the intracranial extension of the tumor. (19 refs)

- 79-5313 Pseudoepitheliomatous Hyperplasia of the External Ear, Middle Ear, and Mastoid. (Eng) Khan, A. S. (4000 Annapolis Road, Baltimore, MD 21227). *Laryngoscope* 89(6, part 1): 984-987; 1979.

The first known case of pseudoepitheliomatous hyperplasia involving the external ear, middle ear, and the mastoid air cells and labyrinth, resulting from long-standing irrigations with alcohol, is reported. The patient, a 57-yr-old man, presented with persistent pain and chronic discharge from the left ear of 45 yr duration. Recommended treatment had been warm soaks and irrigation with rubbing alcohol (ethyl alcohol for 30 yr, isopropyl alcohol for 15 yr). (7 refs)

- 79-5314 Multiple Intramedullary Neurinomas of the Spinal Cord. Case Report. (Eng) Pardatscher, K. (Inst. Neuroradiology and Neurosurgery, Univ. Padova, Padua, Italy); Iraci, G.; Cappellotto, P.; Rigobello, L.; Pellone, M.; Fiore, D. *J Neurosurg* 50(6): 817-822; 1979.

Multiple neurinomas firmly embedded within the nervous substance of the spinal cord and presumably extending over the entire length of its surface developed in a 41-yr-old man. He had a history of continuous severe pain in the thoracic spine for 6 mo and progressive weakness and paresthesia in the lower limbs, wide gait, sexual impotence, and urinary incontinence for 8 wk. The complete lack of a relationship of the multiple lesions with the spinal nerve roots and the absence of any signs of neurofibromatosis were the most salient features of this rare case. The association of the intramedullary neurinomas with the spinal cord, their distribution along its longitudinal axis, and their histopathological features favor the hypothesis that these lesions are an example of neurocristopathy, a term coined to denote a group of dysgenic, hamartomatous, and neoplastic conditions that have as a common pathogenetic factor a disturbance in the development of the neural crest and in the migration of its cells. (28 refs)

- 79-5315** Glomus Jugulare Tumor Presenting with Increased Intracranial Pressure. Case Report. (Eng) Beck, D. W. (Div. Neurosurgery, Univ. Iowa Hosps. and Clinics, Iowa City, IA 52242); Kassell, N. F.; Drake, C. G. *J Neurosurg* 50(6): 823-825; 1979.

A glomus jugulare tumor presenting with papilledema and visual loss developed in a 51-yr-old obese woman. The tumor was extremely vascular, with significant shunting of arterial blood into venous sinuses. There was no intracranial extension of tumor. The fact that the papilledema and high-amplitude intracranial pulsations resolved after tumor removal strongly suggests that the neoplasm was the causative mechanism. The presence of papilledema in association with such a tumor does not necessarily indicate intracranial extension. (5 refs)

- 79-5316** Neurosurgical Desmoid Tumors. Presentation of Four Cases with a Review of the Differential Diagnoses. (Eng) Friede, R. L. (Dept. Neuropathology, Inst. Pathology, Univ. Zurich, Zurich, Switzerland); Pollak, A. *J Neurosurg* 50(6): 725-732; 1979.

The case reports of four patients (females aged 9, 11, 40, and 67 yr) with desmoid neurosurgical tumors are presented, along with a brief review of the differential diagnoses of intracranial or spinal fibromatous or desmoid lesions. Two of the tumors were identified as densely collagenized meningiomas by their typical ultrastructure. The classification of the other two tumors remains uncertain, but they were thought to belong to the family of desmoid tumors. (34 refs)

- 79-5317** Preferential Digestion of Basement Membrane Collagen by an Enzyme Derived from a Metastatic Murine Tumor. (Eng) Liotta, L. A. (Lab. Pathophysiology, NCI, NIH, Bethesda, MD 20014); Abe, S.; Robey, P. G.; Martin, G. R. *Proc Natl Acad Sci USA* 76(5): 2268-2272; 1979.

The specificity of human skin collagenase and of an enzyme from an invasive tumor were studied with the use of native types I, II, III, IV, and V (AB) collagen as substrates. Human skin collagenase degraded types I, II, and III collagen, producing the characteristic 3/4 and 1/4 cleavage products, but it failed to degrade type IV or V collagen. Collagenase prepared from the invasive tumor showed max activity after trypsin treatment. The tumor enzyme degraded type IV (basement membrane) collagen, producing fragments consistent with a single cleavage site, but it did not attack types I, II, III, and V collagen. Because type IV collagen prepared by pepsinization of placenta was also digested, it is likely that cleavage of type IV collagen by the tumor collagenase occurs within a largely helical domain. A type IV collagenase could play a significant role in tumor

metastases and in normal tissues where basement membrane turnover occurs. Preliminary studies indicate that an enzyme degrading type IV collagen is produced by rat breast ducts and involuting breast tissue in culture. (26 refs)

- 79-5318** Erythroleukemia: In Vitro Studies of Erythropoiesis. (Eng) Newcomb, M. M. (Veterans Admin. Hosp., 1500 E. Woodrow Wilson, Jackson, MS 39216); Balducci, L.; Coleman, M. B.; Steinberg, M. H. *Am J Hematol* 5(4): 291-295; 1978.

The growth of erythroid burst-forming units (BFU-E) and erythroid colony forming units (CFU-E) from the bone marrow and blood of six patients with erythroleukemia and controls with no hematologic disorders was studied. One patient had received several courses of chemotherapy. In the controls, the av number of clusters per BFU was 5.3, while in the patients whose marrow grew BFU-E, the av number was 3.2. When erythropoietin was omitted from patient cultures, no colonies formed. Erythropoietin in excess of 4 units/ml for BFU-E and 2 units/ml for CFU-E did not promote additional colony growth. In controls, BFU-E growth was linear with mononuclear cell inputs of $0.5-2.5 \times 10^5$ /culture with erythropoietin concentrations greater than 2 units/ml; these cultures were routinely incubated with 4 units/ml to assure maximal erythropoietin stimulation. (21 refs)

- 79-5319** Squamous Cell Carcinoma Arising in Chronic Osteomyelitis. (Eng) Inglis, A. M. (Div. Orthopedics, Dept. Surgery, Univ. British Columbia, 2740 Heather St., Vancouver, British Columbia V5Z 314 Canada); Morton, K. S.; Lehmann, E. C. *Can J Surg* 22(3): 271-273; 1979.

The occurrence of squamous cell carcinoma (SCC) in an area of chronic osteomyelitis in three patients is reported. A 49-yr-old man who developed osteomyelitis involving the tibia 40 yr earlier and who had suffered a minor injury to the chronically infected limb 2.5 mo earlier presented with a well-differentiated SCC infiltrating the tibia. This case was atypical in that there had been no sinus drainage from the infected limb for 34 yr prior to occurrence of the tumor. A 72-yr-old man who developed hematogenous osteomyelitis of the right leg at age 12 yr presented with SCC on the anterior aspect of the right leg. A 79-yr-old man presented with a well-differentiated, infiltrating SCC on the plantar aspect of his left heel. This patient had suffered from chronic osteomyelitis dating from an injury sustained 46 yr earlier. The development of SCC in areas of chronic osteomyelitis is chiefly a problem in men of middle age or older. The tibia is the site of infection in 50% of these cases. Prognosis is guarded and the treatment of choice is amputation. (9 refs)

79-5320 Cardiac Sarcoma Causing "ASH" and Stimulating Coronary Heart Disease. (Eng)

Isner, J. M. (Pathology Branch, Natl. Heart, Lung, and Blood Inst., NIH, Bethesda, MD 20014); Falcone, M. W.; Virmani, R.; Roberts, W. C. *Am J Med* 66(6): 1025-1030; 1979.

A primary cardiac sarcoma in a 48-yr-old man preferentially infiltrated the ventricular septum while essentially sparing the left ventricular free wall, resulting in striking echocardiographic and morphologic asymmetry between the septum and the free wall (ie, asymmetric septal hypertrophy). No reports have appeared previously of a patient with an intramural cardiac neoplasm demonstrated by an echocardiogram. Clinically, the patient had features typical of coronary heart disease, yet at necropsy the extramural coronary arteries showed insignificant (<75%) cross-sectional area luminal narrowing by atherosclerotic plaques. (17 refs)

79-5321 Multiple Malignant Spiegler Tumors with Brachydactyly and Racket-Nails. Light and Electron Microscopic Study. (Eng)

Tsambaos, D. (Dept. Dermatology, Univ. Gottingen, 34 Gottingen, W. Germany); Greither, A.; Orfanos, C. E. *J Cutan Pathol* 6(1): 31-41; 1979.

The case report of a 67-yr-old woman with multiple malignant Spiegler scalp tumors coincident with brachydactyly on the fifth fingers and racket nails on all fingers is presented, together with light and electron microscopy findings. The occurrence of similar clinical features in the patient's family suggests a hereditary disorder. The microvillous appearance of the cell surface, the incomplete formation of lumina, the accumulation of small vacuoles, and the existence of secretory granules confirmed the sweat gland origin of the scalp tumors. (16 refs)

79-5322 Diagnosis of Lymphoepithelioma of the Nasopharynx. (Rus) Golovin, D. I. (Sanitary-Hygienic Inst., Leningrad, USSR); Smirnova, I. N. *Vopr Onkol* 25(4): 31-35; 1979.

Current data on the histogenesis of lymphoepitheliomas are critically reviewed. A retrospective analysis of the case histories of 43 patients with lymphoepithelioma of the nasopharynx revealed that 34 patients had in fact had poorly differentiated carcinomas with lymphocytic infiltration and 9 patients had an epithelioid variant of reticulosarcoma. It is strongly emphasized that a differential diagnosis between poorly differentiated carcinomas and reticulosarcomas can be made only by examination of serial sections. A diagnosis of lymphoepithelioma is incorrect, as tumors that consist of a mixture of malignant epithelial and malignant lymphoid cells do not exist. (19 refs)

79-5323 Liver-colonizing Melanoma Cells Selected from B-16 Melanoma. (Eng) Tao, T. (Dept. Biochemistry, Biocenter, 4056 Basel, Switzerland); Matter, A.; Vogel, K.; Burger, M. M. *Int J Cancer* 23(6): 854-857; 1979.

A population of B-16 melanoma cells showing an increased tendency to form tumor nodules in the liver following iv and intraarterial injection was selected in vivo from male C57BL/6 mice. The cells were selected by a stepwise procedure: (1) injection of the original cells through the portal circulation; (2) removal of tumor cells from the hepatic tumor nodules for culture in vitro; (3) reinjection of such cells through the portal circulation and repetition of steps 2 and 3 eight times. The predilection of the selected cells to form tumors in the liver was clearly demonstrated following injection of the cells intraarterially. The accuracy of the injection technique was controlled by monitoring amounts of injected radioactively labeled Sephadex microspheres. This liver-colonizing preference was not exclusive, but relative. (9 refs)

79-5324 Hypercalcemia and Malignant Melanoma. (Eng) Burt, M. E. (Surgery Branch, NCI, Building 10, Bethesda, MD 20014); Brennan, M. F. *Am J Surg* 137(6): 790-794; 1979.

The case reports of two men (aged 26 and 37 yr) with malignant melanoma and hypercalcemia are presented. Of 560 melanoma patients examined between 1970 and 1977, 6 (1.1%) had hypercalcemia. Five of these patients had bone metastases and one had primary hyperparathyroidism and metastatic malignant melanoma with no evidence of bone metastases. Of 804 patients with malignant melanoma examined between 1953 and 1977, 42 (5.2%) had bone metastases; serum calcium was not determined. Of the six hypercalcemic patients in the first series, five were men with a mean age of 45 yr (range, 26-83 yr). The mean serum calcium was 14.6 mg/100 ml and the mean serum phosphorus was 3.8 mg/100 ml. Serum parathyroid hormone determinations in three subjects revealed an elevated level in the patient with primary hyperthyroidism but no detectable activity in two patients with bone metastases. Chloride/phosphate ratios correctly differentiated patients with bone metastases from the patient with primary hyperparathyroidism. (20 refs)

79-5325 The Transformation of Laryngeal Leucoplakia to Cancer. (Eng) Henry, R. C. (Withington Hosp., West Didsbury, Manchester M20 8LR, England). *J Laryngol Otol* 93(5): 447-459; 1979.

The transformation of laryngeal keratosis to cancer is discussed. Keratosis is the keratinization of the stratified squamous epithelium of the true vocal cord. Cellular atypia

denotes not only faulty maturation, but also individual cell alterations. The appearance of the full thickness of the epithelium between the intact basement membrane and the surface occupied by atypical cells with total loss of the cytological architecture is carcinoma in situ. An invasive carcinoma occurs when the basement membrane is disrupted and the malignant cells spread down into the underlying stroma. The progress of laryngeal keratosis was studied in 38 men and 5 women aged 25-80 yr; the highest incidence was in the fifth, sixth, and seventh decades of life. Thirty-four patients were smokers. Thirty-eight patients showed no change from laryngeal keratosis to cancer, although two cases progressed to keratosis with atypia. Five patients developed squamous carcinoma. Four of the carcinomas developed from keratosis with atypia and four were invasive. Reports in the literature have identified 18 carcinomas among 135 cases of keratosis with atypia (13.3%); 12 of these were invasive. Only 3 carcinomas developed in 138 patients with keratosis without atypia. Thus, keratosis with atypia can be considered precarcinomatous. (7 refs)

- 79-5326 An Established Lung Cancer Cell Line Producing Colony-stimulating Activity. (Eng) Kimura, N. (First Dept. Internal Medicine, Faculty Medicine, Kyushu Univ., Higashi-ku, Fukuoka, Japan); Niho, Y.; Ono, J.; Miyamoto, N.; Shibuya, T.; Takaki, R. *Proc Jpn Acad* 54(9): 548-552; 1978.

The establishment of a lung cancer cell line with colon-stimulating activity (CSA) is reported. The cell line was derived from the pleural effusion of a patient (44-yr-old man) with undifferentiated giant cell carcinoma and with a high level of CSA in his serum, urine, and pleural effusion. The degree of proliferation of the cultured cells was low in the early period but became more active after 3 mo. The proliferation pattern of the cancer cells (KONT cells) was epithelial. The cell size was varied and numerous granules were seen in the cytoplasm. KONT cells implanted sc in a nude mouse gave rise to a tumor with the same pattern as the giant cell carcinoma seen in the patient. Thus, the KONT cells originated from giant cell carcinoma. A CSA assay of the supernatant of the KONT cell culture revealed a high level of colony formation in human and mouse marrow cells. The KONT cells should be useful in studying the mechanism of granulopoiesis, since they consistently produce markedly high levels of CSA. (9 refs)

- 79-5327 A 46,XY Lung Adenocarcinoma in a 46,XX Female Patient. A Possible Parental Transmission. (Eng) Genest, P. (Dept. Pathology, Faculty Medicine, Laval Univ., Quebec, Quebec G1K 7P4, Canada); Lagace, R.; Bouillant, A.; Dumas, L.; Bonenfant, J. L. *Acta Cytol (Baltimore)* 23(3): 237-244; 1979.

A cell line with an XY complement isolated from a biopsy of a lung adenocarcinoma in a 46,XX female patient (age 50) was characterized. The morphology and secretory properties of the cultured cells were similar to those of the tumor. Study of the chromosomes of 67 cells from the first subculture showed that 43% were diploid or near-diploid and that the others were heteroploid, with a distribution that ranged from 36 to 113 chromosomes. Karyotype analysis of the diploid cells revealed that they had a 46,XY complement. The characteristics of the Y chromosome were ascertained by Q- and C-banding techniques. Numerous chromosome abnormalities that are usually found in neoplastic cells were observed in the heteroploid cells of the culture. The cellular characteristics and chromosome abnormalities confirmed the malignant nature of the cell line. Blood lymphocyte culture demonstrated that the patient had a normal female karyotype (46,XX). Because she had seven normal children, it is hypothesized that the malignant clone could have originated only through the mechanism of dispermy from her father, who died of presumed lung cancer. The neoplastic cell line with the Y marker may have been repressed until recent factors favored its evolution. (15 refs)

- 79-5328 Bronchogenic Carcinoma with Coexisting Active Pulmonary Tuberculosis in Urban Blacks. (Eng) Solomon, A. (Dept. Radiology, Baragwanath Hosp., Johannesburg, S. Africa); Hurwitz, S.; Conlan, A. A. *S Afr Med J* 55(24): 979-981; 1979.

The occurrence of coexisting lung cancer and active pulmonary tuberculosis in black South Africans was studied. Six patients with radiographic evidence of pulmonary disease and *Mycobacterium tuberculosis* in their sputum were found to have squamous bronchogenic carcinoma (3 patients) or adenocarcinoma (3 patients). The patients, five of whom were men, ranged in age from 40 to 75 yr. One was a heavy smoker, four were moderate smokers, and one was a nonsmoker. All showed extensive local tumor spread, distant metastasis, and poor pulmonary function. It is likely that the cancer in such patients activates dormant tuberculosis. In a population with a high incidence of tuberculosis, the heavy smoker in his fifth decade seems particularly vulnerable to the combined diseases. (12 refs)

- 79-5329 Granular Cell Tumor of the Common Bile Duct. Case Report and Review of Literature. (Eng) Jain, K. M. (535 Centre St., Nutley, NJ 07110); Hastings, O. M.; Rickert, R. R.; Swaminathan, A. P.; Lazaro, E. J. *Am J Gastroenterol* 71(4): 401-407; 1979.

The occurrence of a granular cell tumor in the common bile duct (CBD) of a 46-yr-old black woman is reported. The

patient remained asymptomatic after cholecystectomy and duodenotomy. The resected CBD showed the appearance of a typical benign granular cell tumor and the resected gallbladder showed mild chronic cholecystitis. Granular cell tumor of the CBD appears to be prevalent only among blacks, the seven reported cases having ranged in age from 15 to 46 yr. The laboratory studies in five cases, including the present case, were consistent with the diagnosis of obstructive jaundice and/or cholecystitis. However, the preoperative diagnosis of this tumor is difficult because there are no specific features of this disease. The origin of these tumors remains debatable. Granular cell tumors are usually benign, but cases of local recurrence and sometimes distant metastases have been reported. Patients have done well after local excision. (26 refs)

- 79-5330 **Alpha-1-Antitrypsin Deficiency and Hepatocellular Carcinoma.** (Eng) Kelly, J. K. (Dept. Pathology, Univ. Manchester, Stopford Building, Oxford Road, Manchester M13 9PT, England); Davies, J. S.; Jones, A. W. *J Clin Pathol* 32(4): 373-376; 1979.

Paraffin-embedded neoplastic and nonneoplastic tissue blocks from 42 cases of hepatocellular carcinoma (HCC) and 98 control livers were examined for the presence of globular inclusions of α_1 -antitrypsin (AAT). Intrahepatic AAT globules are considered indicative of an AAT deficiency resulting from the presence of the Pi Z allele. The inclusions were found in the nonneoplastic liver tissue of 2 cases of HCC and in 1/98 control livers, a difference that is not statistically significant. Typical globules of AAT deficiency were not found in HCC cells. However, one-fourth of the HCC's contained cells that showed diffuse cytoplasmic staining for AAT, a pattern also seen in the nonneoplastic livers. (22 refs)

- 79-5331 **Quantitative Determination of Serum Carcinoembryonic Antigen (CEA) Levels in Patients with Digestive Tract Tumors.** (Spa) Richart, C. (Ciudad Sanitaria de la Seguridad Social, Universidad Autonoma de Barcelona, Barcelona, Spain); Ruibal, A.; Monne, J.; Guardia, J. *Rev Esp Enferm Apar Dig* 55(1): 23-30; 1979.

Serum CEA levels were determined in 90 patients with carcinomas of the digestive tract. The sensitivity of the method was 2.5 nanograms (ng)/ml. Serum CEA levels >15 ng/ml were considered positive. The frequency of positive CEA tests was 18/20 patients with colorectal carcinoma with metastases, 9/18 patients with colorectal carcinoma without metastases, 5/5 patients with pancreatic carcinoma with metastases, 5/6 patients with pancreatic carcinoma without metastases, 12/13 patients with gastric carcinoma with metastases, 4/9 patients with gastric carcinoma without metastases, 3/3 patients with esophageal

carcinoma with metastases, 3/3 patients with esophageal carcinoma without metastases, 4/4 patients with carcinoma of the gallbladder and bile ducts with metastases, 0/2 patients with carcinoma of the gallbladder and bile ducts without metastases, and 7/8 patients with peritoneal carcinomatosis. The serum CEA levels exceeded 40 ng/ml in 39 cases: 34 patients with metastases (34 cases), 4 patients with peritoneal carcinomatosis, and 1 patient with pancreatic carcinoma without metastasis. (26 refs)

- 79-5332 **Therapeutic Endoscopy of an Abrikosov's Tumor in the Esophagus.** (Ger) Schroder, G. (Paracelsus-Klinik, Am Natruper Holz 69, D-4500 Osnabruck, W. Germany); Kohlmann, H. W. *Z Gastroenterol* 17(5): 281-286; 1979.

An almost pea-sized polypous tumor of the esophagus was found in a 33-yr-old man during esophagogastroscope for occult hypogastric symptoms. Examination of the biopsy sample revealed the presence of an Abrikosov's tumor. The tumor was removed completely by a diathermy loop. Abrikosov's tumors of the esophagus are very rare; only 11 cases, 10 of them benign, have been reported in the literature. (16 refs)

- 79-5333 **Rapidly Progressive Scleroderma Associated with Carcinoma of the Oesophagus.** (Eng) Mattingly, P. C. (Rheumatology Unit, Nuffield Orthopaedic Center, Oxford, England); Mowat, A. G. *Ann Rheum Dis* 38(2): 177-178; 1979.

The case report of a 70-yr-old woman with rapidly progressive scleroderma and esophageal carcinoma is presented. The rapid progression of the scleroderma suggests that scleroderma may occasionally represent a systemic manifestation of malignancy. (8 refs)

- 79-5334 **Multiple Squamous Carcinomas and the Oesophagus.** (Eng) Solomon, A. (Dept. Radiology, Baragwanath Hosp., Johannesburg, S. Africa); Hunt, J. *S Afr Med J* 55(25): 1028-1030; 1979.

Three rare cases of simultaneously appearing double carcinoma of the esophagus, two of which occurred in a group of 383 esophageal squamous carcinoma patients investigated as part of an epidemiological survey, are reported. All three patients were men aged 48-58 yr. Presenting symptoms included dysphagia, chest and epigastric pain, and wt loss. The double carcinomas were revealed by barium swallow examinations. In two patients, the upper polypoidal lesions were successfully biopsied; radiographic demonstration and direct visualization or palpation confirmed the presence of the lower lesions. The

PATHOGENESIS

radiological features of all lesions included an irregular surface, destroyed mucosa, and bulky eccentric masses invading the esophageal lumen. There was a shouldering effect between the affected and the adjacent esophageal segments. The mucosa between the two lesions was radiologically intact. The double carcinomas may represent a primary carcinoma that has undergone intraepithelial esophageal extension or large, secondary, metastatic deposits. (6 refs)

- 79-5335 A Case of Gastric Cancer Arising from a Heterotopic Pancreas in the Gastric Wall. (Jpn) Miyake, H. (Dept. Radiology, Gifu Univ. Sch. Medicine, Maebashi, Gunma Prefecture 371, Japan); Yamawaki, Y.; Matuura, S.; Doi, H.; Yamamoto, M.; Oohashi, H.; Miyashita, T.; Ikeda, T.; Goto, S. *Gan No Rinsho* 25(6): 634-638; 1979.

A 72-yr-old man with a gastric cancer thought to have originated from a heterotopic pancreas in the gastric wall is reported. The tumor protruded slightly into the gastric lumen, destroying a portion of the mucosal layer. It extended across to the transverse colon, infiltrating the submucosa without destroying the integrity of the mucosa. A consistent pattern of pancreatic acinar cells was seen throughout the interstitial spaces of the tumor tissue. On the basis of the microscopic examination, the patient was thought to have a heterotopic acinar cell carcinoma. (13 refs)

- 79-5336 The Sites of Origin of Gastric Cancers and Ulcers in Relation to Mucosal Junctions and the Lesser Curvature. (Eng) Evans, D. M. (Histopathology Dept., Llandough Hosp., Penarth, Cardiff, Wales); Cleary, B. K. *Invest Cell Pathol* 2(2): 97-117; 1979.

To clarify the much-disputed relationship between peptic ulcers and gastric cancers, a histological mapping procedure was used to study 32 stomachs bearing small cancers and 23 stomachs bearing ulcers. Over 80% of the gastric cancers and peptic ulcers occurred within 2 cm of both a mucosal junction and the lesser curvature. They showed slight differences in their longitudinal relationship to the pyloric junction. There were differential characteristics between the groups of cancers arising at each of the three mucosal junctions. Cancers in the pylorus and cardia were more common in men (male:female ratio, 2.6:1) and were predominantly well-differentiated, whereas those in the intermediate zone were more common in women (1:1.8) and were predominantly undifferentiated. These and other features suggest that gastric cancers should be subdivided according to the junction of origin. (35 refs)

- 79-5337 Carcinoid Diathesis of the Ileum. (Eng) Warner, T. F. (Dept. Pathology, Indiana Univ. Sch. Medicine, 1100 W. Michigan St., Indianapolis, IN 46202); O'Reilly, G.; Power, L. H. *Cancer* 43(5): 1900-1905; 1979.

A total of 108 carcinoids were discovered in the ileum of a 63-yr-old man who presented with colicky pain and vomiting for the previous 24 hr. He had had similar pain intermittently for 10 yr. The clustering and size distribution of the tumor nodules suggest that the phenomenon reflects mucosal metastasis from a dominant parent tumor rather than multicentric neoplastic foci. A predilection for the antimesenteric mucosa was also observed, and it may be related to mucosal lymphatic spread of the carcinoid tumor. (39 refs)

- 79-5338 Ureterosigmoidostomy and Carcinoma of the Colon. (Eng) Pierce, E. H. (Dept. Pathology, Univ. Vermont, Burlington, VT); Zickerman, P.; Leadbetter, G. W. *Trans Am Assoc Genitourin Surg* 70: 92-98; 1979.

Two cases of the association of colon carcinoma (CC) with ureterosigmoidostomy (USS) are described, and 45 literature cases are reviewed. The first patient (52-yr-old man) had a single lesion at the site of active urine flow. The second (31-yr-old man) had a lesion at both anastomotic sites, one benign and one malignant. They were located at the site of a functional and nonfunctional ureteral implant, respectively. The etiology for the development of CC associated with USS seems to be related to the urine. The incidence of CC associated with USS is 500 times greater than that in the normal population, indicating a 5% lifetime risk. The development time of these lesions varies from 6 to 50 yr postoperatively, but the development time is significantly less in patients >40 yr old. The possibility exists that CC may develop in primary sigmoid urinary diversion conduits or in sigmoid internal conduits to either the bladder or bowel. There have been no reports of bowel carcinoma in an ileal urinary diversion. Follow-up evaluation should include examination of stools for blood every 3 mo after 2 yr, excretory urogram yearly after 5 yr, sigmoidoscopy or colonoscopy every 5 yr, and barium enema every 5 yr. If the patient has hematochezia or the excretory urogram demonstrates ureteral obstruction, sigmoidoscopy and colonoscopy should be done. (37 refs)

- 79-5339 A Case of Mucinous Carcinoma of the Descending Colon Associated with *Schistosoma japonicum* Infection. (Jpn) Naito, H. (Second Dept. Surgery, Kurume Univ. Sch. Medicine, Kurume 830, Japan); Isomura, T.; Okabe, M.; Kojiro, M.; Iwamoto, G.; Misoguchi, M. *Gan No Rinsho* 25(4): 325-328; 1979.

A combination of mucinous carcinoma and *Schistosoma japonicum* infection was observed in the descending colon of a 77-yr-old man who presented with an intestinal obstruction. The schistosomiasis was initially diagnosed 20 yr previously. A limited degree of atypical cellular proliferation was seen in the mucosa, but primary tumor involvement occurred in the submucosa, muscle layer, and serosa. Numerous nodules formed by *S. japonicum* ova were observed in the submucosa. Mucin-producing cystic cells that had infiltrated from the serosa were found in the muscle layer. The epithelial cells lining the cysts found in the muscle layer were mixed with atypical epithelial cells of the mucosa in papillary structures. The features of ulcerative colitis associated with *S. japonicum* infection and with colon cancer are reported to be the same. Mucin production is often increased in adenocarcinoma and ulcerative colitis patients. The simultaneous occurrence of increased mucin production, ulcerative colitis, and both cystic and adenocarcinoma cells accompanying the schistosomiasis in this patient is considered significant in linking *S. japonicum* and carcinogenesis. (14 refs)

- 79-5340 Neuroblastoma. Report of One Case. (Ita) Cavaliere, A. (Istituto di Anatomia e Istologia Patologica, Università di Perugia, Perugia, Italy); Bacci, M.; Moretti, A. *Pathologica* 71(1011): 115-119; 1979.

A tumor of the right iliac fossa was found in a 6-mo-old boy. The resected tumor was diagnosed as a Wilms' tumor of the right kidney. Another tumor, interpreted as a local recurrence with mesenteric spread and liver metastasis, developed 3 mo later. At autopsy, this tumor was identified histologically as a large neuroblastoma originating from the sympathetic nervous system. (13 refs)

- 79-5341 Morphologic Classification of Inflammatory, Nonspecific, and Proliferative Lesions of the Urinary Bladder of Mice. (Eng) Frith, C. H. (Pathology Services Project, Natl. Center Toxicological Res., Jefferson, AR 72079). *Invest Urol* 16(6): 435-444; 1979.

A morphologic classification of inflammatory, nonspecific, and proliferative lesions of the mouse urinary bladder was developed based on examinations of approx 75,000 mice. Acute inflammation is characterized by the presence of neutrophils in the lumen and/or mucosa and lamina propria, and chronic cystitis is associated with numerous mononuclear cells infiltrating the lamina propria and/or muscle coat. Nonspecific lesions include vacuolization of the transitional epithelium, squamous metaplasia, crystalluria, urinary calculi, and dystrophic mineralization. Proliferative lesions include simple and papillary hyperplasia of the transitional epithelium; nodular hyperplasia; diverticula, usually of the ureters or urethra; papillary and nonpapillary carcinomas (transitional, transi-

tional with squamous metaplasia, squamous cell, undifferentiated, and adenocarcinoma); infiltrative lesions (stage O, A, B, C, and D); primary mesenchymal tumors (vascular, muscular, fibrous connective tissue, and other); and metastatic tumors. (22 refs)

- 79-5342 Polyps of the Urethra in Children. (Eng) Zachwiej, J. (Urological Clinic, Postgraduate Medical Education Centre, Warsaw, Poland); Witeska, A. *Int Urol Nephrol* 11(1): 49-55; 1979.

The case reports of two boys, aged 12 mo and 15 yr, with urethral polyps are presented. The patients presented with urinary retention or dysuria. In both cases, the polyp was excised along with the peduncle. In the first patient, microscopic examination revealed that the polyp was fibrous and partially covered with transitional epithelium, partially with squamous epithelium. In the second patient, the polyp was of the urethral glandular type. (8 refs)

- 79-5343 Pathogenesis of Colonic Polyps in Multiple Juvenile Polyposis. Report of a Case Associated with Gastric Polyps and Carcinoma of the Rectum. (Eng) Goodman, Z. D. (Dept. Pathology, Johns Hopkins Hosp., Baltimore, MD 21205); Yardley, J. H.; Milligan, F. D. *Cancer* 43(5): 1906-1913; 1979.

The pathogenesis of juvenile polyps of the colon was studied in a 23-yr-old woman with multiple juvenile polyposis who underwent proctocolectomy for rectal carcinoma and antrectomy for associated polyps of the stomach. Numerous polyps up to 3 cm in diameter were present predominantly in the cecum and rectum; in addition, there was an adenocarcinoma in the rectum. Microscopically, there were five categories of lesions: (1) hyperplastic epithelial foci and small hyperplastic polyps; (2) typical juvenile polyps; (3) juvenile polyps with focal adenomatous epithelium; (4) adenomas; and (5) an adenocarcinoma. The five categories could represent a pathogenetic sequence, beginning with epithelial hyperplasia and leading to small hyperplastic polyps that become inflamed and enlarge, forming juvenile polyps. Focal adenomatous areas that develop in some juvenile polyps might give rise to adenomas and, in turn, lead to carcinoma. Although juvenile polyps are generally not considered to be premalignant lesions, this case demonstrates that neoplastic changes may occur in juvenile polyps in certain individuals and it raises the possibility that they may, on occasion, give rise to carcinoma. (9 refs)

- 79-5344 Metastatic Colonization Potential of Primary Tumour Cells in Mice. (Eng) Tarin, D. (Dept. Histopathology, John Radcliffe Hosp., Headington, Ox-

ford, England); Price, J. E. *Br J Cancer* 39(6): 740-754; 1979.

A model has been developed for studying the capability of cells from primary murine mammary tumors to establish colonies in distant organs. The model involves the iv inoculation of disaggregated tumor cells into autologous and syngeneic recipients. There were sharp differences in the colonization potential of primary tumors inoculated into CBA/lac mice: extensive replacement of lung tissue by large colonies of tumor with high colonization potential (HCP) was observed in 37% of the animals; and tumors of low colonization potential (LCP) formed few or no lung colonies (63% of the animals). There was no direct relationship between grade of colonization and survival time in that some animals with Grades IV and V were still alive and apparently well at 90 days. However, there was a tendency for groups with very heavy colonization results to die before the end of the experimental period. There were no characteristic features in common between tumor deposits in organs other than the lungs. The findings in DBA₂ mice were similar to those in CBA/lac animals. The incidence of metastasis from undisturbed murine mammary tumors was less than 2%. There was no correlation between tumor size or morphologic features and colonization potential. Both histologic and electron microscopic observations indicated the mammary origin of the lung tumor tissue. (11 refs)

79-5345 Gonadoblastoma Associated with Malignant Teratoma. (Eng) Luzzatto, R. (Dept. Pathology, Univ. Texas System Cancer Center, MD Anderson Hosp. and Tumor Inst., 6723 Bertner, Houston, TX 77030); Murray, J. M.; Gallager, H. S. *South Med J* 72(5): 624-627; 1979.

Gonadoblastoma associated with malignant teratoma in the contralateral ovary occurred in a 19-yr-old girl. A karyotype of the peripheral blood lymphocytes was 46 XY; there were no individual chromosome abnormalities. The risk of development of a malignant gonadal neoplasm in XY gonadal dysgenesis is sufficiently high to justify prophylactic gonadectomy. (10 refs)

79-5346 Feminizing Thecal-Granulosa Cell Tumor of the Ovary with Pseudopubertas Praecox. (Spa) Vinuela, A. (Residencia Sanitaria de la S. S. "Virgen Blanca", Leon, Spain); Manero, S.; Toyos, J. M.; Fernandez-Rojo, F.; Martinez-Merino, A. *Tokoginecol Pract* 37(414): 89-104; 1978.

An ovarian tumor was suspected in an 8-yr-old girl showing signs of pseudopubertas praecox. She presented with acute abdomen, abdominal tumor, and oliguria. A pedicled tumor of the right ovary was found. Right salpingo-oophorectomy was performed. The estrogen levels were

normal 31 mo after the surgery, at which time the patient had not yet reached puberty. The tumor was identified histologically as a unilateral, feminizing, thecal granulosa cell tumor of the macrofollicular and microcystic type, with predominant thecal elements. There were no Call-Exner bodies or massive edema in the stroma, but the tumor did show signs of luteinization. (45 refs)

79-5347 Familial Carcinoma of the Ovary: Case Report. (Eng) Philipp, E. E. (Royal Northern Hosp., London, England). *Br J Obstet Gynaecol* 86(2): 152-153; 1979.

The case report of a 53-yr-old woman who developed a poorly differentiated cystadenocarcinoma of the ovary is presented. Family history revealed that of 10 women at risk in two generations, 5 (including this patient) had developed ovarian carcinoma. They were the patient's mother, her mother's sister, that sister's daughter, and another maternal aunt's daughter. (11 refs)

79-5348 Five Metachronous Malignant Neoplasms: A Follow-up Report. (Eng) Russell, J. M. (Dept. Surgery, Section Urology, North Carolina Baptist Hosp., Winston-Salem, NC 27103); Myers, R. T.; Harrison, L. H. *NC Med J* 40(5): 284-285; 1979.

The case report of a 66-yr-old woman who had five separate sequential malignancies over a 17-yr period is presented. She had an adenocarcinoma of the uterus, transitional cell carcinoma of the left renal pelvis and ureter, transitional cell carcinoma of the right ureter, adenocarcinoma of the transverse colon, and adenocarcinoma of the hepatic flexure. The cause of the increased susceptibility is unclear, although a defect in immunologic surveillance must be considered. (12 refs)

79-5349 A Woman with Acanthosis Nigricans Maligna, a Paraneoplastic Syndrome. (Dut) Oranje, A. P. (Afdelingen Dermatologie, Academisch Ziekenhuis Rotterdam Dijkzigt, Rotterdam, Netherlands); Smit, A. F.; Vuzevski, V.; Stolz, E. *Ned Tijdschr Geneesk* 123(19): 789-791; 1979.

An 81-yr-old woman developed acanthosis nigricans maligna in the lips and in the axilla about 4.5 mo after hysterectomy for a moderately differentiated endometrial adenocarcinoma. No virus particles were found in the biopsy specimen from the lip. The patient died of the adenocarcinoma; acanthosis nigricans disappeared during the terminal stage. (11 refs)

- 79-5350 A Further Cytogenetic Study of Hydatidiform Mole, with Reference to its Androgenetic Origin. (Eng) Wake, N. (Dept. Obstetrics and Gynecology, Sch. Medicine, Hokkaido Univ., Sapporo, Japan); Shiina, Y.; Ichinoe, K. *Proc Jpn Acad* 54(9): 533-537; 1978.

A cytogenetic analysis was performed on six hydatidiform mole conceptuses and their parents. Molar tissues were removed from the uterine cavity and cultured in minimal essential medium supplemented with 20% fetal calf serum in 5% carbon dioxide in air. The six cases were characterized by a normal female karyotype (46,XX), and their parents were also chromosomally normal. Six pairs of marker chromosomes (3, 13-15, 21-22) were scored for Q-band polymorphism. The Q-banded chromosomal features in cells from the six moles had uniform homozygosity in members of each pair, but the parental karyotypes had at least one pair that was heterozygous. With one exception, neither of the maternal homologs was transmitted to moles in 10 identified pairs of chromosomes; while both members of 8 homologs identified in moles were traceable only to one of the corresponding paternal homologous chromosomes. These findings suggest that the moles received a paternal haploid set in duplicate, but none from the mother. The chromosomes from four primary and metastatic chorionic tumors were investigated recently. They were characterized by a high incidence of cells in the tetraploid range, and the homologous chromosomes of certain pairs with polymorphic chromosome variants were not morphologically identical. These findings do not support the view of cellular continuity between moles and choriocarcinoma. (12 refs)

- 79-5351 Sarcoma of the Vulva. (Fre) Guerard, M. J. (Departement de Pathologie, Hopital Notre-Dame, Montreal, Canada); Paquin, F.; Audet-Lapointe, P.; Charbonneau, A. *Union Med Can* 108(5): 501-505; 1979.

A 48-yr-old woman developed a rapidly growing tumor in the labium majus. She developed a recurrence 2 yr after simple resection. The tumor was diagnosed as a leiomyosarcoma of the vulva. Radical vulvectomy and lym-

phadenectomy were performed. The resected lymph nodes were free from metastasis. This is the seventh case of vulvar leiomyosarcoma reported in the literature. (24 refs)

- 79-5352 Simultaneous Prostatic Carcinoma and Genital Paget's Disease Associated with Subjacent Adenocarcinoma. (Eng) Oka, M. (Dept. Urology, Kumamoto Chuo Hosp., 1-16-1, Shinyashiki, Kumamoto 862, Japan); Saita, B.; Nakashima, K. *Br J Urol* 51(1): 49; 1979.

The case report of a 65-yr-old man with prostatic carcinoma and extramammary Paget's disease of the scrotal skin is presented. In addition, nests of adenocarcinoma were found in the dermis of the scrotum underneath the Paget's cells. (3 refs)

EPIDEMIOLOGY AND BIOMETRY

- 79-5353 Sequential Pathogenic Components of Rates. (Eng) Morrison, A. S. (Dept. Epidemiology, Harvard Sch. Public Health, 677 Huntington Ave., Boston, MA 02115). *Am J Epidemiol* 109(6): 709-718; 1979.

A relationship was derived between rates of sequential pathogenic transitions and the corresponding overall rate of disease. The av duration of the entire natural history of a disease is the sum of the average durations of all of its stages. The rate of termination of each stage is inversely related to the duration of the stage; the overall rate for a disease with multiple stages is the reciprocal of the total average duration of the natural history. The overall rate for multiple stages must be less than the lowest component transition rate. Thus, for any particular disease, the mortality rate is less than both the incidence rate among the well and the rate of death among the diseased. The incidence rate is less than both the rate of preclinical disease development and the rate of transition from preclinical disease to clinical. A change in the rate of one transition, such as that of cancer initiation, will be underestimated by the corresponding change in and overall rate such as the incidence rate. Similarly, a change in an incidence rate will be underestimated by the respective change in the overall mortality rate. The max change in an overall rate due to any degree of change in one transition rate is limited by the size of other rates in the sequence. (16 refs)

- 79-5354 Estrogen Replacement Therapy II: A Prospective Study in the Relationship to Carcinoma and Cardiovascular and Metabolic Problems. (Eng) Nachtigall, L. E. (Dept. Obstetrics and Gynecology, New York Univ. Medical Center, New York, NY 10016); Nachtigall, R. H.; Nachtigall, R. D.; Beckman, E. M. *Obstet Gynecol* 54(1): 74-79; 1979.

A 10-yr double-blind prospective study was undertaken to evaluate the effects of estrogen replacement therapy (ERT). The sample population consisted of 84 pairs of randomly chosen postmenopausal in-patients, matched for age and diagnosis. The treatment group received conjugated estrogen (Premarin: 2.5 mg/day) and medroxyprogesterone acetate (Provera: 10 mg/day) for 7 days in each month; the controls received placebos. The results revealed no statistically significant difference in the incidence of thrombophlebitis, myocardial infarction (MI), or uterine cancer. There was a lower incidence of breast cancer in the treated group. The estrogen-treated patients had a higher incidence of cholelithiasis. Those in the

treated group who began the study with elevated beta/alpha lipoprotein ratios showed a reduction in that ratio over the course of the study. In the control group, these ratios remained constant or increased. The low number of cases precludes drawing any real significance from the data on diseases of low frequency. The study excludes only a high incidence of complications from estrogens. (26 refs)

- 79-5355 Multiple Malignancies in Patients with Primary Carcinomas of the Head and Neck. (Eng) Weichert, K. A. (Dept. Radiotherapy, Univ. Cincinnati Coll. Medicine, Cincinnati, OH 45267); Schumrick, D. *Laryngoscope* 89(6, part 1): 988-991; 1979.

Of 825 patients with primary carcinomas of the head and neck registered with the Head and Neck Tumor Services at the University of Cincinnati Medical Center Affiliated Hospitals, 54 had multiple primaries. Synchronous lesions occurred in 19, nonsynchronous lesions in 35. The secondary tumor sites were the head and neck (33), lung (12), esophagus (4), and rectum, prostate, stomach, and breast (5). All 54 patients had continued to drink or smoke after the original diagnosis, leading to the conclusion that as long as the carcinogenic agent (alcohol/tobacco) continues to be present, the patient will continue to be affected. (12 refs)

- 79-5356 Chronic Alcoholism and Subsequent Mortality in World War II Veterans. (Eng) Robinette, C. D. (Medical Follow-up Agency, Natl. Academy Sciences-Natl. Res. Council, 2101 Constitution Ave., Washington, DC 20418); Hrubec, Z.; Fraumeni, J. F. *Am J Epidemiol* 109(6): 687-700; 1979.

Mortality during 1946 through 1974 among 4,401 US Army servicemen hospitalized for chronic alcoholism in 1944-1945 was compared with that of individually age-matched subjects hospitalized for nasopharyngitis. The relative risk of death from all causes for the alcoholism vs the nasopharyngitis admissions was 1.87 ($p < 0.001$). The relative risks were significantly high for death due to alcoholism (12.8), tuberculosis (10.2), alcoholic cirrhosis (3.5), trauma (3.1), nonmalignant diseases of the esophagus, stomach, and duodenum (2.5), ill-defined causes of death (2.1), nonmalignant respiratory diseases including pneumonia (1.7), and ischemic heart disease (1.4). A significant excess risk was also noted for brain cancer

and for diseases of the liver or gallbladder (other than cancer or cirrhosis), but relative risks could not be estimated because no deaths occurred in the nasopharyngitis group. The risk for all cancers combined was significantly related to alcoholism (1.6, $p < 0.01$) only among subjects discharged to duty or separated from service for disability, and not among those separated administratively for having undesirable character traits. (34 refs)

- 79-5357 Patterns of Incidence of Brain Tumors in Children. (Eng) Gold, E. B. (Dept. Epidemiology, Johns Hopkins Univ. Sch. Hygiene and Public Health, Baltimore, MD 21205); Gordis, L. *Ann Neurol* 5(6): 565-568; 1979.

A population-based community-wide study of the incidence of brain tumors in children during 1960-1974 was conducted in the Baltimore area. Incidence rates in boys declined over the study period, and the rates were higher in whites than in blacks in all age groups except children < 5 yr. A peak in incidence rates was observed in white 5- to 9-yr-olds and in blacks from 0 to 4 yr of age. In addition, incidence rates tended to be higher in boys than in girls at all ages except puberty (the 10- to 14-yr-old age group) when rates in girls exceeded those in boys. The findings suggest that both host and environmental factors may be involved in the development of brain tumors in children. (13 refs)

- 79-5358 Leukemia in Benzene Workers. (Eng) Infante, P. F. (Industry-wide Studies Branch, Div. Surveillance, Hazard Evaluation and Field Studies, Natl. Inst. Occupational Safety and Health, Center Disease Control, Cincinnati, OH 45202); Rinsky, R. A.; Wagoner, J. K.; Young, R. J. *J Environ Pathol Toxicol* 2(5, Special): 251-257; 1979.

Workers occupationally exposed to benzene during 1940-1949 at two Ohio plants were followed for vital status up to 1975. In comparison with two control populations, a significant ($p < 0.002$) excess of leukemia was observed. The study population had a fivefold excessive risk of all leukemias and a tenfold excess of deaths from myeloid and monocytic leukemias combined, compared with controls. These figures underestimate the true leukemia risk to benzene-exposed workers, because follow-up was only 75% complete and the untraced 25% were all regarded, in the statistical analysis, as being alive at the end of the study period. The environment of the workers in the study population was not contaminated with solvents other than benzene, and existing records indicate that the benzene levels themselves were generally below the limits recommended at the time they were measured. (22 refs)

- 79-5359 Leukemia from Atomic Fallout (Letter to Editor). (Eng) Bader, M. (2305 N.W. 94th Street, Seattle, WA 98117). *N Engl J Med* 300(26): 1491-1492; 1979.

Mortality from childhood leukemia in Seattle-King County, Washington varied considerably between 1950 and 1972. Only 27% of children studied in a review of leukemia in Washington state from 1956-1961 were ever exposed to x-rays, and most of these exposures were minimal. Evaluation of age-specific leukemia death rates for children in Utah showed no increases in mortality and no distinct relation to radioactive fallout over Utah at any time since 1950. It is suggested that a previous study proposing an association between childhood leukemia and fallout from nuclear testing represents an overinterpretation of limited data. (no refs)

- 79-5360 Pregnancy, Breast-Cancer Risk, and Maternal-Fetal Genetics (Letter to Editor). (Eng) Janerich, D. T. (Bureau Cancer Control, New York State Dept. Health, E.S.P. Tower Building, Albany, NY 12237). *Lancet* 1(8128): 1240-1241; 1979.

Epidemiological data supporting the hypothesis that immune suppression during pregnancy increases the risk of breast cancer (BC) in the short run and decreases it in the long run are defended. Reexamination of current registry data by 1-yr intervals shows that until 40 yr of age, there is a lower proportion of single women among BC cases compared with other cancers. After age 40, the excess begins to appear. In terms of age-specific rates and proportions of single women, there is evidence of a cross-over of incidence associated with marital status for women in their mid- to late 30's that is presumably pregnancy-related. (2 refs)

- 79-5361 Mortality Patterns among Workers in a Gray Iron Foundry. (Eng) Decoufle, P. (Environmental Epidemiology Branch, NCI, 3C07 Landow Building, Bethesda, MD 20014); Wood, D. J. *Am J Epidemiol* 109(6): 667-675; 1979.

The long-term mortality experience of 2,861 men employed for at least 1 mo during 1938-1967 in a US gray iron foundry was examined. Both white and nonwhite workers experienced favorable mortality for most major disease categories compared with the general population rates, even men employed ≥ 5 yr. No deaths from pneumoconiosis were observed, and there were no excess deaths from other chronic respiratory diseases. Analysis of detailed cancer sites showed no significant departures from expected overall values. However, in the subgroup of men who were employed ≥ 5 yr prior to 1938, a twofold increase in mortality from digestive cancer (14 observed deaths vs 7.4 expected) and respiratory cancer (8 observed deaths vs

4.0 expected) was seen. The absence of information on specific foundry jobs held by the subjects and on associated exposures limits full interpretation of the findings. However, the excess observed for respiratory cancer among long-term employees followed for 30 yr is consistent with previous reports. (27 refs)

79-5362 Patterns and Determinants of Conjugated Estrogen Use. (Eng) Rosenberg, L. (Drug Epidemiology Unit, Boston Univ. Medical Center, 10 Moulton St., Cambridge, MA 02138); Shapiro, S.; Kaufman, D. W.; Slone, D.; Miettinen, O. S.; Stolley, P. D. *Am J Epidemiol* 109(6): 676-686; 1979.

The ambulatory use of conjugated estrogens (CE's) in the Greater Boston area is described based on data collected from hospitalized women. In addition, geographic and temporal variation in use was evaluated using prescription survey data from various areas of the US. Among 1,273 women aged 30-69 yr of age interviewed in Greater Boston hospitals, there were 161 ever-users of CE's; 88 had used the drug within the preceding year. The median duration of use was 3 yr. Prominent determinants of use were age, menopause, and history of menopausal symptoms. Physician prescription survey data from an independent source suggest that CE use has been common throughout the US, and that it may have declined after reports linking CE's to endometrial cancer were published in 1975. If CE use indeed increases the risk of endometrial cancer some fivefold, an important public health problem exists. (20 refs)

79-5363 Mortality Patterns among Miners and Millers of Non-asbestiform Talc: Preliminary Report. (Eng) Selevan, S. G. (Industry-Wide Studies Branch, Div. Surveillance Hazard Evaluations and Field Studies, Natl. Inst. Occupational Safety and Health, Rockville, MD 20857); Dement, J. M.; Wagoner, J. K.; Froines, J. R. *J Environ Pathol Toxicol* 2(5, Special): 273-284; 1979.

Mortality and environmental assessments were made of workers exposed to talc free of asbestos and of significant quantities of free silica. This population was drawn from Vermont Health Department records of employees of five companies in three geographic locations. Mortality patterns were assessed from January 1, 1940, through December 31, 1975, and cause-specific expected numbers of deaths were calculated from white male rates for the US and Vermont, using a modified life table technique. Excess nonmalignant respiratory disease mortality was observed in millers, a group thought to have greater lifetime dust exposures than miners. No such excess was observed among miners. Excess lung cancer mortality was observed in the miners, but expected deaths were small and exposures other than talc are suspect for this excess. Past talc exposure

levels often far exceeded the present Occupational Safety and Health Administration and the Mining Enforcement and Safety Administration Standard of 20 mppcf for non-fibrous talc (<1% free SiO₂). Analyses of current airborne dust samples and talc bulk samples showed talcs from all locations in the currently operating mines and mills studied to be similar in composition. No asbestos was detected in any of the samples analyzed by x-ray diffraction or electron microscopy. Levels of free silica in bulk samples were <0.25% for nearly all samples, and only in occasional air samples was free silica detectable. Talc shards and ribbons were seen in talc bulk and airborne dust samples. In addition to talc, other minerals present in these ores in significant quantities included magnesite, chlorite, and dolomite and to traces of calcite, biotite, ankerite, and phlogopite. (26 refs)

79-5364 A Preliminary Report of Mortality Patterns among Foundry Workers. (Eng) Egan, B. (Div. Surveillance, Hazard Evaluations and Field Studies, Industry-wide Studies Branch, Natl. Inst. Occupational Safety and Health, Cincinnati, OH 45202); Waxweiler, R. J.; Blade, L.; Wolfe, J.; Wagoner, J. K. *J Environ Pathol Toxicol* 2(5, Special): 259-272; 1979.

A proportional mortality study of US foundry workers was conducted utilizing the death records maintained from 1971 to 1975 by the International Molders and Allied Workers Union as part of a death benefits program. Death certificates were obtained for 3,013 members of the study group and classified by a trained nosologist. The age- and race-specific cause distribution of all deaths among men in the US for 1973 was used as a standard from which expected deaths were calculated. The statistical significance of differences between observed and expected numbers of deaths was determined by a chi-square test. The most statistically significant finding was an excess lung cancer mortality (208 observed vs 142 expected) and an excess mortality due to pneumoconiosis (29 observed vs 5 expected). Potential agents found in the foundry environment that may be responsible for the increased lung cancer risk include aromatic hydrocarbons, polynuclear aromatic hydrocarbons, nitrosamines, bis(chloromethyl)ether, talc, and asbestos. 79-5365 Effects of Tobacco Smoking and Other Irritating Factors on the Laryngotracheal Mucosa. (Pol) Chodynicky, S. (Klinika Otolaryngologiczna, Instytut Chorob Nerwowych i Narzadow Zmyslow Ak. Med., ul. Parkowa 14 m. 70, 15-224 Bialystok, Poland); Tupalska, M. *Wiad Lek* 32(5): 299-304; 1979.

Epidemiological, clinical, and morphological studies of the epiglottis and trachea were performed in 100 patients (99 men, 1 woman aged 35-59 yr) operated on for laryngeal

carcinoma. The carcinoma was located in the supraglottic part of the larynx in 76 patients, in the glottis in 24. Ninety-six patients were cigarette smokers: 81% had been smoking for >30 yr, the others >20 yr. Forty percent of the smokers smoked 30-40 cigarettes/day, the others more than 20. Ninety-two patients were also exposed occupationally to irritating factors involved in construction work, manufacture of machinery, transportation, and agriculture. Morphological investigations revealed multilayered squamous cell epithelium in the epiglottis. The tracheal mucosa showed signs of inflammation, epithelial damage, and transformation of multilayered columnar epithelium into multilayered squamous epithelium. Atypical cells were also found in some patients. (23 refs)

- 79-5366 Influence of 3,4-Benzopyrene in Falling Dust on the Incidence of Neoplastic Diseases of the Respiratory System in Inhabitants of the City of Szczecin. (Pol) Pilawska, H. (Zaklad Higieny, Pomorska Akademia Medyczna, Szczecin, Poland); Skucinski, S.; Soroka, M.; Rymgayllo, B. *Ochrona Powietrza* 2: 29-34; 1979.

Correlations between the tar and 3,4-benzopyrene (BP) content of falling dust and the incidence of neoplasms of the respiratory tract were studied in Szczecin during a 12-mo period (1975-1976). The dustfall (in ton/km²) as well as the tar and BP content of the dust showed considerable variation in time and space; the dustfall was highest in the summer, the tar and BP content of the dust in the winter. The tar content in the dust ranged from 4.3 to 122.1 mg/g, and the BP content from 0.085 to 0.654 mg/g, averaging 0.256 mg/g for all 10 monitoring sites representing 10 areas of the city. The comparison of the tar and BP levels in the dust with the incidence of neoplasms of the respiratory tract showed no correlation; there was no increase in the incidence in the areas with the highest exposure to BP. - 79-5367 Some Aspects of Suberosis--A Respiratory Disease Affecting Cork Industry Workers. (Por) Avila, R. (Clinica Universitaria de Doenca Pulmonares, Hospital de Santa Maria, Lisbon, Portugal). *Hisp Med* 36(417): 103-132; 1979.

A detailed study of suberosis in cork industry workers is presented. The association of suberosis with alveolar cell carcinoma was found in a 53-yr-old man who had been working at a cork processing plant for 13 yr and who smoked about 15 cigarettes a day for 30 yr. Cork particles were found in the lung carcinoma. (no refs)

- 79-5368 Lung Cancer in Malaysia. (Eng) Menon, M. A. (Dept. Medicine, Univ. Hosp., Kuala Lumpur, Malaysia); Saw, H. S. *Thorax* 34(2): 269-273; 1979.

Between 1967 and 1976, 388 lung cancer patients were seen at the University Hospital, Kuala Lumpur, 72% of whom had histological confirmation of their disease. Most were aged 50-80 yr, and the male:female ratio was 2.8:1. The patients were predominantly of Chinese origin (82%) and from the lower socioeconomic strata. A history of smoking was elicited in 78%. Only 2% were asymptomatic; 70% presented with a history of <6 mo duration. Most had cough, hemoptysis, wt loss, and dyspnea. The chief radiological features and the diagnostic methods are presented. The various histological types included squamous carcinoma (34%), adenocarcinoma (25%), large cell carcinoma (12%), small (oat) cell carcinoma (12%), "undifferentiated/anaplastic" carcinoma (15%), and others (2%). Malays appeared to have a higher percentage of adenocarcinoma. A comparison between the histologically confirmed group and the remaining patients showed no significant differences in features. (12 refs)

- 79-5369 Occupational Lung Cancer. (Nor) Kreyberg, L. (Munkedamsveien 79, Oslo 2, Norway). *Tidsskr Nor Laegeforen* 99(12): 570-574; 1979.

Epidemiological data on lung cancer in Norway are presented, and the contributions of occupational hazards and smoking to lung cancer are discussed. In the urban male population of Norway, the yearly lung cancer mortality rate was 2/100,000 population in the mid-1930's, 25 in the mid-50's, and 50 in the mid-70's. In the rural male population, the mortality was 2/100,000 in the mid-30's, 5 in the mid-50's, and 20 in the mid-70's. This increase paralleled an increase in the percentage of smokers in the rural population. While exposure to asbestos, uranium, and chromium increases the risk and incidence of lung cancer, smoking habits are also a factor. Thus, incidence and mortality rates are influenced not only by working conditions, but also by the specific smoking habits of individual occupational groups. Considerable differences were found between different occupational groups with regard to the percentages of smokers, the amount of tobacco used per day, and the ratio of cigarette smokers to pipe smokers. In groups with no, or negligible, exposure to specific occupational carcinogens, lung cancer incidence increased with an increase in the percentage of smokers, in tobacco consumption, and in the ratio of cigarette to pipe smokers. The relative risk of lung cancer was calculated to be 1.4 for nonsmokers exposed to asbestos, 12 for smokers without asbestos exposure, and 17 for smokers exposed to asbestos. (14 refs)

- 79-5370 No Lung Cancer in Schizophrenics (Letter to Editor)? (Eng) Coakley, D. V. (55 Rodney Street, Liverpool 1, England). *Br J Psychiatry* 134: 649; 1979.

Over a 5-yr period, eight cases of lung cancer in schizophrenics were confirmed in the postmortem records of a single hospital. Histologically, the tumors were oat cell carcinomas, poorly differentiated squamous carcinomas, and a well-differentiated papillary adenocarcinoma. (no refs)

- 79-5371 Carcinoma of the Lung in Lancashire Coalminers. (Eng) Rooke, G. B. (Pneumoconiosis Medical Panel, Manchester, England); Ward, F. G.; Dempsey, A. N.; Dowler, J. B.; Whitaker, C. *J. Thorax* 34(2): 229-233; 1979.

The incidence at death of lung carcinoma in coal miners and exminers was compared in those with and without pneumoconiosis (PC) at necropsy. Of the 1,003 deaths analyzed, 114 cases of lung carcinoma were found, an incidence (11.4%) no greater than that in the male population in Northwest England. Lung carcinoma was present in 62 (13.1%) of the miners and exminers without PC and in 52 (9.8%) of those with PC. The mean age at death of those with PC was 71.3 yr, so they did not die before the age at which they would have developed carcinoma. Miners and exminers with progressive massive fibrosis whose mean age at death was 72 yr had the lowest prevalence of lung carcinoma at all ages, 8.4%. For reasons stated in the text, this is inevitably a biased sample. The number of those without PC is probably lower than the true figure, because the deaths of miners and exminers in whom there was no suspicion of lung disease may not have been reported to the coroner or to the PC medical panel. There appears to be no positive link between lung carcinoma and PC. There was a surprisingly high number of smokers and exsmokers among the miners, and this finding appears to have more relevance to the incidence of lung carcinoma in this group than does PC. (15 refs)

- 79-5372 Variations in the Incidence and the Spatial Distribution of Patients with Primary Acute Pancreatitis in Nottingham 1969-76. (Eng) Bourke, J. B. (Dept. Surgery, General Hosp., Nottingham NG1 6HA, England); Giggs, J. A.; Ebdon, D. S. *Gut* 20(5): 366-371; 1979.

During 1969-1976, 214 patients with primary acute pancreatitis were admitted to hospitals in the Nottingham, England area. In one patient, pancreatic carcinoma was an etiological factor. An analysis of the distribution of pancreatitis patients according to six water supply areas showed that the number of patients from a particularly hard water area was significantly greater than could have occurred by chance. (28 refs)

- 79-5373 Epidemiology of Cancer of the Pancreas. (Fre) Audigier, J. C. (Centre d'Epidemiologie du CNRS LP 005440, Faculte de Medecine, avenue Rockefeller, 69373 Lyon Cedex 2, France); Lambert, R. *Ann Gastroenterol Hepatol (Paris)* 15(3): 159-162; 1979.

The pancreatic cancer mortality rate in France is 6/100,000 men and 3/100,000 women, and it accounts for 3% of the overall cancer mortality. An increased incidence of pancreatic cancer was seen in cigarette smokers, diabetics, and workers exposed to β -naphthylamine and benzidine. Methylnitrosourea, methylnitrosourea, 2,2'-dihydroxy-N-propylnitrosamine, and 7,12-dimethylbenz(a)anthracene induced pancreatic cancer in experimental animals. (27 refs)

- 79-5374 Primary Liver Tumors Due to Estrogen-Progestogen Preparations: Results of an Open Survey in France. (Fre) Rauber, G. (Laboratoire d'Anatomie Pathologique, CHU de Brabois, route de Neufchateau, F 54500 Vandoeuvre, France); Meot, B. *Nouv Presse Med* 8(23): 1945; 1979.

A tumor registry was established in 1978 to record primary liver tumors associated with the use of estrogen-progestogen compounds. Among women aged 15-50 yr seen by 315 participating French physicians since January 1975, 26 cases, including 2 malignant tumors, were recorded as of March 1979. (1 ref)

- 79-5375 An Epidemiological Study of Hepatic Tumor Incidence in Subjects Working with Trichloroethylene. I. Negative Results of Retrospective Investigations in Subjects with Primary Liver Carcinoma. (Cze) Novotna, E. (Centrum hygieny prace a nemoci z povolani, Institut hygieny a epidemiologie, Srobarova 48, 100 42 Prague 10, Czechoslovakia); David, A.; Malek, B. *Prac Lek* 31(4): 121-123; 1979.

Fifty-six patients with primary liver carcinoma were investigated retrospectively for occupational exposure to trichloroethylene. The patients included 39 men (av age 69 yr) and 17 women (av age 56 yr). The analysis failed to reveal a history of trichloroethylene exposure in any of the subjects. One patient had been exposed to radioactive substances in a watch factory. (6 refs)

- 79-5376 An Epidemiological Study of Hepatic Tumor Incidence in Subjects Working with Trichloroethylene. II. Negative Results of Retrospective Investigations in Dry Cleaners. (Cze) Malek, B. (Hygienicka stanica hl. m. Prahy, Rytirska 12, 110 00 Prague 1, Czechoslovakia); Kromarova, B.; Rodova, O. *Prac Lek* 31(4): 124-126; 1979.

The incidence of primary liver cancer was studied in 57 dry cleaners who had been exposed to trichloroethylene (TCE) for 1-35 yr (60% for >5 yr). The age of the subjects ranged from 25 to 85 yr, with 80% aged >45 yr. The exposure of the subjects to TCE was considerable: urinary trichloroacetic acid concentrations exceeded 100 mg/liter in 60% of those tested, and concentrations up to 1,000 mg/liter were found sporadically. No case of liver cancer was found in this group, but cancers of other organs were found in six men aged 58-75 yr (length of exposure 3-34 yr). This incidence corresponds to the incidence of cancer in this age group in general. Three patients had lung cancer, one had carcinoma of the palate and tongue, one had rectal carcinoma, and another had carcinomas of the urinary bladder and rectum. (1 ref)

- 79-5377 Primary Malignant Lymphoma of the Stomach, Analysis of 38 Cases. (Ger) Klaiber, H. (Pathologisches Institut, Kantonsspital Winterthur, Winterthur, Switzerland); Sulser, H.; Ruttner, J. R.; Kobler, E.; Deyhle, P. *Schweiz Med Wochenschr* 109(18): 668-675; 1979.

A retrospective analysis of 38 cases of malignant lymphoma of the stomach is presented. The patients included 18 men and 20 women. Lymphocytic lymphomas were diagnosed in 3 men and 3 women (av age 56 yr), lymphoblastic lymphomas in 2 men and 4 women (av age 54 yr), mixed-cell lymphomas in 4 men (av age 58 yr), reticulum-cell lymphomas in 7 men and 13 women (av age 63 yr), and Hodgkin's disease in 2 men (av 48 yr). There were no significant differences in symptomatology between lymphoma and carcinoma of the stomach. However, signs of stenosis were missing in the lymphoma patients, even though most of the tumors were located in the antrum. Due to the extreme tendency of the lymphomas to ulcerate (89%), the mean duration of symptoms was only 2.5 mo. Diffuse infiltrative growth was seen in most cases; the tumor extended to the serosa in 19 cases. Tumor size, determined in 35 cases, averaged 7.5 cm. Half of the patients had clinical stage I E at the time of operation. The prognosis was generally best for lymphocytic lymphoma and worst for reticulum-cell lymphoma and lymphoblastic sarcoma. (34 refs)

- 79-5378 Clinicopathological Study of 180 Patients with Early Gastric Cancer. (Jpn) Naito, H. (Second Dept. Surgery, Kurume Univ. Sch. Medicine, Kurume, Fukuoka Prefecture 830, Japan); Kasahara, Y.; Komura, T.; Miyoshi, A.; Nakayama, Y.; Kunitake, K.; Yoshida, K.; Nakayama, T.; Isomura, T.; Okabe, M.; Arakawa, M.; Kojiro, M. *Gan No Rinsho* 25(6): 583-591; 1979.

A total of 180 patients with early stage gastric cancer were classified by Nakamura's system. There were 108 cases of

differentiated cancer in 101 patients (29 women, 72 men; av age 59.9 yr) and 79 cases of undifferentiated cancer in 79 patients (42 women, 37 men; av age 49.9 yr). The differentiated cancers usually occurred on the antrum or on the medial part of the stomach, and they were either protruded or depressed. The undifferentiated cancers usually occurred in the medial part of the stomach, and most of them were depressed. The differentiated types were localized and they tended to invade the serosa; the undifferentiated types tended to invade the mucosa. Ulcers occurred in 38 differentiated cancer patients and 55 undifferentiated cancer patients; the latter showed a higher susceptibility to ulceration, which was considered to be a secondary pathological condition. Examination of the epithelial changes in the surrounding nonmalignant intestinal mucosa of 95 patients with gastric cancer of the mucosal layer (<4 cm deep) confirmed Nakamura's concept that differentiated cancer follows epidermal transformation of the intestinal mucosa and undifferentiated cancer originates from the gastric mucosa. (15 refs)

- 79-5379 Ten-Year Relative Survival Rate for Stomach Cancer: Comparison of Stomach Cancer Discovered by Mass Screening or in Outpatient Clinics. (Jpn) Sugahara, N. (Cancer Detection Center, Miyagi Cancer Society, Miyagi Prefecture, Japan); Hisamichi, S.; Masuda, Y.; Yanbe, T.; Sakuma, A. *Gan No Rinsho* 25(6): 577-582; 1979.

The postoperative 10-yr survival rates of 391 patients whose stomach cancer was discovered by mass screening (S) and 176 patients whose stomach cancer was discovered in an outpatient clinic (O) were compared. Early stage cancers were found in 82 S and 34 O patients, advanced stage cancers in 270 S and 114 O patients. The 10-yr relative survival rates (actual survival rate/expected survival rate) was 47.4% for S and 33.1% for O. A correlation between the depth of tumor infiltration and relative survival rate showed that there were no significant differences between groups S and O at tumor depths reaching the mucosa, submucosa, muscle layers, or subserosa. There was a marked difference in 10-yr survival rates between the groups when the tumors invaded the serosa (S 30%, O 10.7%). The prognosis of S patients was significantly better ($p < 0.05$) than the prognosis of O patients. (21 refs)

- 79-5380 Primary Occult Tumor of the Ovary. (Jpn) Moriwaki, S. (Dept. Pathology, Matsuyama Natl. Hosp., Matsuyama, Japan); Takashima, S.; Kitajima, T.; Kojima, Y.; Chiba, T.; Kubo, T.; Hayashi, S. *Gan No Rinsho* 25(6): 598-604; 1979.

The frequency and histogenesis of occult ovarian tumors were determined among 3,348 ovaries obtained by surgery for nonovarian disease (carcinoma of the uterine cervix and

EPIDEMIOLOGY AND BIOMETRY

corpus, uterine leiomyoma, oophorectomized breast cancer) or at autopsy from 1,982 patients over the past 11 yr. Benign cystic lesions, including 18 dermoid cysts, were seen in 296/3,348 ovaries. The benign solid tumors that were found included 32 fibromas and/or fibromyomas, 43 Brenner tumors, 2 theca cell tumors, 2 cavernous hemangiomas, and 1 struma ovarii associated with a dermoid cyst. Only one intermediate-type tumor, a granulosa cell tumor, was found. No occult malignant neoplasms were found except for 60 metastatic ovarian tumors; 50 of these tumors were found at autopsy. (14 refs)

- 79-5381 Clinical Statistics on Outpatients During the First Year of Operation of the Hamamatsu University Urology Clinic. (Jpn) Aso, Y. (Dept. Urology, Faculty Medicine, Hamamatsu Univ., Hamamatsu, Japan); Fujita, K.; Tajima, A.; Suzuki, K.; Omi, Y.; Ohta, N. *Acta Urol Jpn* 25(4): 375-378; 1979.

The first-year statistics on outpatients treated at a Japanese urology clinic are reported. Of the 661 patients (455 men, 206 women) treated, 37 (33 men, 4 women) had malignant neoplasms. These included tumors of the bladder (16), prostate (10), testis (4), kidney (3), and renal pelvis, penis, urethra, and retroperitoneum (1 each). (no refs)

- 79-5382 Neoplastic Tumors of the Ovary in Young Women. (Spa) Garcia-Calderon, S. (Facultad de Medicina, Universidad de Barcelona, Barcelona, Spain); Marquez Ramirez, M.; Balasch, J.; Iglesias Guiu, J. *Acta Ginecol (Madr)* 34(1): 25-38; 1979.

During a 7.5-yr period, 92 ovarian tumors were found in 86 women aged <30 yr. Eleven patients (with 11 tumors) were aged 14-19 yr (Group 1), 39 patients (with 42 tumors) were aged 20-24 yr (Group 2); and 36 patients (with 39 tumors) were aged 25-29 yr (Group 3). Potentially malignant borderline tumors were found in 1/11 cases in Group 1, 3/42 cases in Group 2, and 2/39 cases in Group 3. Malignant tumors were found in 4/42 cases in Group 2. The tumors included 22 serous and/or papillary cystadenomas, 2 adenofibromas, 2 serous papillary borderline cystadenomas, 9 mucinous cystadenomas, 4 borderline mucinous cystadenomas, 1 mucinous cystadenocarcinoma, 18 endometrial cysts, 27 benign cystic teratomas, 1 struma ovarii, 3 dysgerminomas, and 2 thecomas. (14 refs)

- 79-5383 Epidemiological Study of Endometrial Carcinoma. (Ita) Rendina, G. M. (I Divisione di Ostetricia e Ginecologia, Ospedale San Camillo De Lellis, Rome, Italy). *Riv Ital Ginecol* 58(3): 153-173; 1979.

The results of a retrospective epidemiological study of 912 cases of endometrial carcinoma diagnosed during 1960-1977 and 100 healthy control women are presented in connection with the recent observation of accompanying endocrinopathy with prevalent dysmetabolic manifestations in patients with endometrial carcinoma. The incidence of obesity was 574/912 vs 41/100; that of the combination of obesity, arterial hypertension, and diabetes, 122/912 vs 4/100. Estrogen therapy was given at one time or another in 663 carcinoma cases, vs 66 controls, with a duration of >3 yr in 491 and 26 cases, respectively. One hundred and four patients and 49 controls received estrogen therapy without estrone; the other patients received conjugated estrogens containing estrone or estrone alone, as compared to 17 controls. The risk factors calculated are 2.5 for obesity; 3 for the combination of obesity, arterial hypertension, and diabetes; 1.37 for estrogen treatment in general; 4.4 for long-term estrogen treatment; and 15.4 for estrone treatment. (38 refs)

- 79-5384 Analysis of Anamnestic Data of Patients with Acute Leukemia. (Pol) Osechin'skii, I. V. (Dept. Epidemiology and Histopathology Leukemia, Central Inst. Hematology and Blood Transfusion, A-167, Novozhikovskii pr. 4, Moscow, USSR); Iashanova, N. D.; Serdobol'ski, V. I.; Kuropteva, I. S. *Acta Haematol Pol* 10(1): 23-30; 1979.

The computerized analysis of qualitative and quantitative anamnestic data concerning 200 children with acute leukemia (108 boys and 92 girls) and 217 healthy children (controls) is presented. The data included information on chronic diseases of the parents, toxemia during pregnancy, number of pregnancies, infectious childhood diseases, allergic reactions, asphyxiation, complications of childbirth, malformations, wt and height at birth, and development. As a result of the computer analysis, 181/200 patients and 204/217 controls were classified correctly. The mean error of the classification was 7.75%. (7 refs)

- 79-5385 Radiation Risk in X-Ray Diagnosis in the Gastrointestinal Tract? (Ger) Vogel, H. (Abteilung Röntgendiagnostik, Universitätsklinik Hamburg, Martinistr. 52, 2000 Hamburg 20, W. Germany). *Roentgenblaetter* 32(6): 314-318; 1979.

The somatic and genetic risks of diagnostic x-ray examinations of the gastrointestinal tract were calculated. The somatic risk, expressed as the number of fatal malignancies or leukemias due to the diagnostic procedure per number of examinations, was found to be highest for angiography (1/25,000), but only 1/300,000-800,000 for diagnostic examinations of the stomach, duodenum, small intestine and colon and for endoscopic retrograde cholangiopancreatography. The genetic risk (risk of malformations) in

the children and grandchildren was highest in the offspring of women subjected to angiography (1/2,300) and of men subjected to radiographic examination of the colon (1/4,300). The genetic risk was generally higher in the offspring of female patients (1/2,300-72,000) than of male patients (1/4,300-280,000). (30 refs)

- 79-5386 Mortality and Morbidity During 13.5 Years' Follow-up in Relation to Blood Pressure. (Eng) Svardsudd, K. (Section Preventive Cardiology, Dept. Medicine I, Sahlgrenska Sjukhuset, Goteborg, Sweden); Tibblin, G. *Acta Med Scand* 205(6): 483-492; 1979.

A study of 855 men born in 1913 revealed a strong association between blood pressure and mortality, regardless of the cause of death. The mortality rate from cancer tended to increase with increasing systolic blood pressure, but the relationship was not consistent in the group with the highest systolic pressure (≥ 175 mm Hg), and it was not significant. There was a significant correlation between diastolic pressure and mortality from cancer ($p \leq 0.05$). (51 refs)

- 79-5387 Applied Diagnostic Techniques: A Decisive Factor in the Long-Term T-Year Survival Rate in Prostatic Carcinoma. (Eng) Trasti, H. (Dept. Urology, Sahlgrenska Sjukhuset, Goteborg, Sweden); Nilsson, S.; Peterson, L. E. *Br J Urol* 51(2): 135-139; 1979.

Data from the Swedish Cancer Registry were used to calculate the incidence, age-adjusted incidence, mortality, and age-adjusted mortality for prostatic carcinoma diagnosed between 1958 and 1971. The correlation coefficient between the proportion of patients diagnosed by cytology only and the age-adjusted incidence was highly significant ($p < 0.001$). The long-term T-year survival rate reflects a complex interplay of multiple factors, including diagnostic technology and techniques for staging and grading. The increase in the reported incidence of prostatic carcinoma in Sweden during this period is discussed in terms of the changes in methods of treatment, diagnosis, and analysis of epidemiological data. (13 refs)

- 79-5388 Tumors of Testis in Jamaica. (Eng) Rao, A. B. (Dept. Surgery, Univ. West Indies, Kingston 7, Jamaica); Sparke, B. *Br J Urol* 51(2): 151-153; 1979.

The incidence of testicular tumors in Jamaica from June 1958 to June 1977 was studied. There were 26 reported

cases, giving a world standardized incidence of 0.40/100,000/yr. Ten patients were aged 30-50 yr and 7 were > 60 yr. In all but one patient, the presenting symptom was swelling of the testis. Two-thirds of the patients had regional node involvement or distant metastases at the time of presentation. The tumors examined histologically included 13 seminomas, 5 embryonic carcinomas, 1 teratoma, 1 Leydig cell tumor, and 1 lymphosarcoma. The Jamaican tumor incidence was higher than that of African blacks but lower than that of North American blacks. The peak age incidence was a decade later than that commonly seen in high-incidence countries. (12 refs)

- 79-5389 Smoking Habits of Bladder Cancer Patients: An Attempt to Quantify Tar Exposition. (Ger) Vutuc, C. (Hygiene-Institut, Universitat Wien, Kinderspitalgasse 15, A-1095 Vienna, Austria); Kunze, M. *Aktuel Urol* 10(3): 159-162; 1979.

The smoking habits of 150 men with cancer of the urinary bladder were studied. One hundred and thirty patients (av age 68.7 yr) were cigarette smokers (the av length of smoking was 42.7 yr), 1 was a pipe smoker, and 19 were nonsmokers. In the general population, the percentage of smokers and former smokers among men aged > 50 yr is 74.5%, ie, significantly lower. Among the cancer patients, 98% of the smokers smoked nonfilter cigarettes with a high tar content (> 25 mg) most of the time or exclusively (47%). In 52% of the cases, the last brand smoked was in this category. Of all brands smoked, the high-tar brands were smoked longest (av 37.4 yr). None of the smokers tended to prefer brands with the lowest tar content (< 15 mg). Although sales of high-tar cigarette brands have decreased in Austria during the last several years, this trend was not applicable to the bladder cancer patients. The findings indicate that the risk of bladder cancer can be reduced substantially by reducing the tar exposure of the smokers, ie, by banning high-tar cigarette brands. (11 refs)

- 79-5390 Metastases in Dermatological Patients with Squamous Cell Carcinoma. (Eng) Moller, R. (Dept. Dermatology, Finsen Inst., 49 Strandboulevard, DK-2100 Copenhagen, Denmark); Reymann, F.; Hou-Jensen, K. *Arch Dermatol* 115(6): 703-705; 1979.

A follow-up study of 211 Danish patients with histologically confirmed squamous cell carcinoma (SCC) diagnosed between 1950 and 1959 was performed. There were 141 men of average age 65.5 yr and 70 women of average age

65.3 yr. Metastases were found in nine men (6.3%) and two women (2.8%). Of the tumors localized to sun-exposed skin, 10/188 metastasized; and 6/55 lip tumors metastasized. All patients with metastases had died, most within 2 yr of diagnosis, eight of them directly from the SCC with metastases. No metastases were found in 40 patients in whom the initial diagnosis of SCC was not confirmed by histologic review. These results and the literature data indicate that three groups of SCC (mucocutaneous, primary cutaneous, and cutaneous secondary to inflammatory and degenerative processes) should be distinguished according to respective incidence of metastases (11%, 3%, and 10%-30%). Skin SCC should be considered a malignant tumor with a higher incidence of metastases than previously assumed. (17 refs)

- 79-5391 Teratocarcinoma Cells as Vehicles for Introducing Mutant Genes into Mice. (Eng) Mintz, B. (Inst. Cancer Res., Fox Chase Cancer Center, 7701 Burholme Ave., Philadelphia, PA 19111). *Differentiation* 13(1): 25-27; 1979.

The possibility of using cultured teratocarcinoma cells as vehicles for introducing specific mutant genes into mice is discussed. Some of the chief methods by which this may be accomplished are summarized. Of particular interest is the feasibility of constructing mouse models of human genetic diseases. The introduction of markers such as hypoxanthine phosphoribosyltransferase deficiency or chloramphenicol resistance into teratocarcinoma cells are examples of selective schemes upon which experimental production of teratocarcinoma mutant cells can be based. (12 refs)

- 79-5392 5'-Nucleotidase Levels in Permanent Human Lymphoid Cell Lines and Its Implications for Cell Proliferation (Meeting Abstract). (Eng) Sun, A. S. (Dept. Neoplastic Diseases, Mount Sinai Sch. - 79-5393 Metabolism of S-Adenosylhomocysteine and S-Tubercidinylhomocysteine in Neuroblastoma Cells. (Eng) Crooks, P. A. (Dept. Pharmacology, Yale Univ. Sch. Medicine, New Haven, CT 06510); Dreyer, R. N.; Coward, J. K. *Biochemistry* 18(12): 2601-2609; 1979.

The metabolism of the methylase product inhibitor S-adenosylhomocysteine (SAH) and its 7-deaza analog S-tubercidinylhomocysteine was studied in cultured N-18 neuroblastoma cells. The latter compound, designed to resist metabolic degradation, was inert under conditions in which SAH was rapidly and extensively degraded. Analyses of the products by high-performance liquid chromatography indicated that the primary route of [¹⁴C]SAH metabolism in the cells leads to adenosine. This product did not accumulate; it was rapidly converted to nucleosides or oxypurines by the action of adenosine kinase and adenosine deaminase, respectively. The presence of the potent adenosine deaminase inhibitor coformycin led to a pronounced inhibition of oxypurine formation, an increase in nucleotide formation, and a slight accumulation of the primary metabolic products adenosine and adenine. (52 refs)

- 79-5394 Cellular Dynamics of Neuronal Cells. The Organization of CSK in Neuroblastoma cells. (Eng) Isenberg, G. (Max Planck Inst. Psychiatry, Munich, W. Germany). *Protides Biol Fluid Proc Cbllq* 26: 595-598; 1978.

The organization of the cytoskeleton in neuroblastoma cells was studied. In the advancing growth cone of a developing neurite, actin filaments were the only filamentous components, and they showed at least two supramolecular aggregation states: a planar filament meshwork and paracrystalline-like filament bundles corresponding to microspikes. Unidirectional polymerization of actin may constitute the primary force-producing mechanism for the advancement of the growth cone. In response to concanavalin A (Con A), neuroblastoma cells underwent marked morphologic changes involving the retraction of neurites and the induction of broad and extensive lamellar regions around the cell periphery. Vinblastine or colchicine caused gradual disintegration of neurites but had no effect on the formation of lamellae. The membranes formed on the induced lamellar regions lacked receptors to Con A from the onset of lamellar formation. Actin appears to be involved in the traction of surface receptors. In the shafts of mature neurites, filamentous actin was restricted specifically to the region just below the plasma membrane. Microtubules were abundant in the core of total neurites, and they could be followed for 10 μ m; 100-A filaments were absent from the growth cones. (5 refs)

- 79-5395 The Effect of Vitamin A on the Migration and DNA Synthesis of Rat Bladder Tumor Cell Line NBT II In Culture. (Eng) Tchao, R. (Dept. Pathology, Medical Coll. Pennsylvania, 3300 Henry Ave., Philadelphia, PA 19129); Leighton, J. *Invest Urol* 16(6): 476-482; 1979.

The effect of vitamin A on the migration and DNA synthesis of cultured rat bladder tumor cells (line NBT II) was studied. In the presence of vitamin A (2.5-100 units/ml), the NBT II cells grew as a monolayer with diminished piling up. Keratinization, which normally appeared within stratified cells in postconfluent cultures, was inhibited. A "wounding" technique suitable for quantitative analysis of cell migration was developed for confluent cultures grown on glass coverslips. Vitamin A treatment enhanced the migration of cells from the wound edge. In dense postconfluent monolayer cultures, vitamin A treatment maintained a higher percentage of cells in DNA synthesis

MISCELLANEOUS

than that found in the control cultures, as determined by ^3H -thymidine uptake and autoradiography. In sparse cultures, vitamin A did not stimulate DNA synthesis or increase the mitotic index. This stimulatory effect, limited to dense cultures, may be attributable to vitamin A causing viable cells to be shed into the medium, thereby maintaining the monolayer just at confluence. Thus, vitamin A inhibits squamous cell differentiation, enhances migration, and maintains the culture in the proliferative phase. In a different system of high cell density--NBT II aggregates cultured in a combined matrix of chick plasma clot and collagen-coated sponge--vitamin A also enhanced cell migration. These results may explain, in part, the failure of vitamin A to inhibit the growth of some established tumors completely. (30 refs)

- 79-5396 Pyrimidine Pathway Variants of Cultured Mouse Lymphoma Cells with Altered Levels of Both Orotate Phosphoribosyltransferase and Orotidylate Decarboxylase. (Eng) Levinson, B. B. (Howard Hughes Medical Inst. Lab., Univ. California, San Francisco, San Francisco, CA 94143); Ullman, B.; Martin, D. W. *J Biol Chem* 254(11): 4396-4401; 1979.

The isolation and characterization of stable mouse T-lymphoma (S49) cell variants which have altered levels of both orotate phosphoribosyltransferase and orotidylate decarboxylase are reported. These clones were selected for resistance to either 6-azauridine or 5-fluorouracil, two toxic pyrimidine analogs. The cells of one clone, AU-11, are 10-fold more resistant to 6-azauridine than wild type S49 cells and were shown to possess 4 to 6 times higher levels of both orotate phosphoribosyltransferase and orotidylate decarboxylase. Conversely, the cells of a second clone, FU1-2, are resistant to 5-fluorouracil and show a 50% reduction in the levels of both of these enzymes compared to the wild type enzyme levels. This is the first description of the isolation and characterization of mammalian cell variants or mutants with altered activities of the enzymes in the second half of the pyrimidine pathway. The structural and regulatory properties of orotate phosphoribosyltransferase and orotidylate decarboxylase from these clones have been examined. The affinities of orotate phosphoribosyltransferase and orotidylate decarboxylase for autologous substrates, as well as their heat stabilities, isoelectric points, and feedback inhibition by nucleotides are unaltered in these cell types. In addition, the rate of *de novo* pyrimidine biosynthesis, the activity of the glutamine-dependent carbamyl phosphate synthetase, and steady state levels of uridine triphosphate and cytidine triphosphate are essentially unchanged in the variant cells. These presumed mutants provide useful tools for the understanding of the control mechanisms involved in pyrimidine biosynthesis. (43 refs)

- 79-5397 The Effect of Long-Term Food Restriction on Tumours in Rodents. (Eng) Tucker, M. J. (Imperial Chemical Industries Ltd., Pharmaceuticals Div., Mereside, Alderley Park, Macclesfield, Cheshire SK10 4TG, England). *Int J Cancer* 23(6): 803-807; 1979.

The effects of relatively small reductions in food intake (approx 20%) on the spontaneous tumor incidence in closed colonies of specific-pathogen-free (SPF) Alderley Park strain I rats and SPF Alderley Park strain I Swiss mice were studied. Dietary restriction (DR) significantly retarded mortality in the mice but not in the rats. Fibrous tumors of the skin in male rats and pituitary and mammary adenomas in the female rats were significantly reduced by DR, as were hepatomas in the male mice and pituitary adenomas in the female mice. Tumors of the Harderian gland, testes, and thymus in the mice and, possibly, brain tumors in the rat appeared to be unaffected by DR, which suggests that they may have a different, perhaps viral, etiology. - 79-5399 Lipid Composition of Human Malignant Melanoma Tumors at Various Levels of Malignant Growth. (Eng) Portoukalian, J. (Laboratoire de Physiologie Generale et Comparee, Universite Claude-Bernard, 43 Boulevard du 22 Novembre 1918, F-69621 Villeurbanne, France); Zwingelstein, G.; Dore, J. F. *Eur J Biochem* 94(1): 19-23; 1979.

The lipid pattern of 13 human melanomas from various tissues was investigated. Differences in lipid composition were mainly due to neutral lipid levels, particularly the triacylglycerol fraction, which varied from 88% of the total lipids in one tumor to trace amounts in another. However, the fatty acid pattern of this fraction was not significantly different among the tumors, with palmitic and oleic acids being the major components. In the seven tumor samples in which the percentage of malignant melanocytes relative to the total cell population was known, there was a reverse correlation between the proportion of malignant cells and their neutral lipid level. The cholesterol and phospholipid levels were constant among the tumors investigated, as was the molar ratio of cholesterol to phospholipid. The ganglioside pattern was similar in all samples, and GM₃, GM₂, and GD₃ were the major components. There was no correlation between tumor stage and ganglioside pattern. (24 refs)

79-5400 Neoplastic and Nonneoplastic Lesions in Aging F344 Rats. (Eng) Goodman, D. G. (Clement Associates, Inc., 1010 Wisconsin Ave., NW, Washington, DC 20007); Ward, J. M.; Squire, R. A.; Chu, K. C.; Linhart, M. S. *Toxicol Appl Pharmacol* 48(2): 237-248; 1979.

Neoplastic and nonneoplastic lesions in untreated F344 rats used as controls in carcinogenesis tests sponsored by the National Cancer Institute's Carcinogenesis Testing Program over the last 6 yr were tabulated and evaluated. The most common neoplasms in 1,794 male rats were testicular

interstitial cell tumors, leukemias, pituitary adenomas, and adrenal pheochromocytomas. In 1,754 female rats, common tumors were pituitary adenomas, mammary fibroadenomas, uterine endometrial stromal polyps, and leukemias. A variety of less common and rare tumors were seen in almost every tissue. A few malignant neoplasms were metastatic. Nonneoplastic lesions included nephropathy, cardiomyopathy, focal hyperplasias in a variety of tissues, and inflammatory lesions of the uterus. The focal hyperplasias were suggestive of the early stages of neoplasia in the lung, liver, pituitary, adrenal, thyroid, and testis. (17 refs)

LIBRARY OF G. I. URBANA - CHICAGO

1. The first part of the paper is devoted to a general discussion of the problem of the existence of solutions of the system of equations (1) for arbitrary values of the parameters α and β . It is shown that the system has solutions for arbitrary values of the parameters α and β if and only if the condition $\alpha + \beta = 1$ is satisfied.

2. In the second part of the paper the problem of the existence of solutions of the system of equations (1) for arbitrary values of the parameters α and β is solved. It is shown that the system has solutions for arbitrary values of the parameters α and β if and only if the condition $\alpha + \beta = 1$ is satisfied.

3. In the third part of the paper the problem of the existence of solutions of the system of equations (1) for arbitrary values of the parameters α and β is solved. It is shown that the system has solutions for arbitrary values of the parameters α and β if and only if the condition $\alpha + \beta = 1$ is satisfied.

4. In the fourth part of the paper the problem of the existence of solutions of the system of equations (1) for arbitrary values of the parameters α and β is solved. It is shown that the system has solutions for arbitrary values of the parameters α and β if and only if the condition $\alpha + \beta = 1$ is satisfied.

5. In the fifth part of the paper the problem of the existence of solutions of the system of equations (1) for arbitrary values of the parameters α and β is solved. It is shown that the system has solutions for arbitrary values of the parameters α and β if and only if the condition $\alpha + \beta = 1$ is satisfied.

6. In the sixth part of the paper the problem of the existence of solutions of the system of equations (1) for arbitrary values of the parameters α and β is solved. It is shown that the system has solutions for arbitrary values of the parameters α and β if and only if the condition $\alpha + \beta = 1$ is satisfied.

7. In the seventh part of the paper the problem of the existence of solutions of the system of equations (1) for arbitrary values of the parameters α and β is solved. It is shown that the system has solutions for arbitrary values of the parameters α and β if and only if the condition $\alpha + \beta = 1$ is satisfied.

8. In the eighth part of the paper the problem of the existence of solutions of the system of equations (1) for arbitrary values of the parameters α and β is solved. It is shown that the system has solutions for arbitrary values of the parameters α and β if and only if the condition $\alpha + \beta = 1$ is satisfied.

9. In the ninth part of the paper the problem of the existence of solutions of the system of equations (1) for arbitrary values of the parameters α and β is solved. It is shown that the system has solutions for arbitrary values of the parameters α and β if and only if the condition $\alpha + \beta = 1$ is satisfied.

GENERAL INFORMATION

CARCINOGENESIS ABSTRACTS makes available abstracts, annotations or citations of significant carcinogenesis articles collected from the current major biomedical sources of world literature. This service is provided by the National Cancer Institute through a contract with the Franklin Research Center for preparation of the publication, under Contract No. NOI-CP-75885 with the National Cancer Institute, U.S. Department of Health, Education and Welfare. Published and distributed by the Franklin Institute PressSM.

SUBSCRIPTIONS

For sale by The Franklin Institute Press, Box 2266, Philadelphia, PA 19103. Subscription rate for Volume 17, consisting of 12 monthly issues and a cumulative index is \$75.00, Domestic and \$90.00, Foreign. Check should be made payable to The Franklin Institute Press.

Maruzen Co., Ltd., 3-10, Nihonbashi 2-Chome, Tokyo 103, Japan, is the exclusive distributor of CARCINOGENESIS ABSTRACTS in Japan.

LIBRARY U. OF I. URBANA - CHAMPAIGN

GENERAL INFORMATION

CARCINOGENESIS ABSTRACTS makes available abstracts, annotations, or citations of significant cancer articles collected from the current major biomedical sources of the world literature. This service is provided by the National Cancer Institute through a contract with Franklin Research Center for preparation of the publication.

FREQUENCY OF PUBLICATION: *CARCINOGENESIS ABSTRACTS*, Volume 17, is published in 12 monthly issues with indexes, plus a cumulative index.

ABBREVIATIONS

JOURNAL names are abbreviated according to the *List of Journals Indexed in Index Medicus, Abbreviation Listing*. If the journal is not listed in this, abbreviations are derived from the *International List of Periodical Title Word Abbreviations*.

LANGUAGE of the article is indicated in parentheses after the title and is represented by a three-letter code. The source for these codes is *MARC Manuals Used by the Library of Congress*, pages 183-187.

ABBREVIATIONS used in abstracts:

A	angstrom(s)	mOsm	milliosmolar
ACTH	adrenocorticotrophic hormone	max	maximum
ADP	adenosine diphosphate	mEq	milliequivalent(s)
AMP	adenosine monophosphate	min	minute(s)
ATP	adenosine triphosphate	ml	milliliter(s)
approx	approximately	μl	microliter(s)
av	average	mm	millimeter(s)
BCG	bacillus Calmette-Guerin	mo	month(s)
bid	twice daily	mol wt	molecular weight
C	degree(s) centigrade	N	normal concentration
cal	calorie(s)	NAD	nicotinamide adenine dinucleotide
kcal	kilocalorie(s)	NADH	reduced nicotinamide adenine dinucleotide
cc	cubic centimeter(s)	NADP	nicotinamide adenine dinucleotidephosphate
Ci	curie(s)	NADPH	reduced nicotinamide adenine dinucleotidephosphate
mCi	millicurie(s)	NCI	National Cancer Institute
μCi	microcurie(s)	NIH	National Institutes of Health
cm	centimeter(s)	PAS	periodic acid-Schiff
CNS	central nervous system	po	orally
cpm	counts per minute	ppb	parts per billion
DNA	deoxyribonucleic acid	ppm	parts per million
ED₅₀	median effective dose	qid	four times daily
EDTA	ethylenediamine tetraacetic acid	qod	every other day
g	gram(s)	QO₂	oxygen quotient
kg	kilogram(s)	R	roentgen
mg	milligram(s)	RBC	red blood cells (erythrocytes)
μg	microgram(s)	RNA	ribonucleic acid
Hb	hemoglobin	rpm	revolutions per minute
hr	hour(s)	sc	subcutaneous
ia	intra-arterial	sec	second(s)
id	intra-dermal	SGOT₁	serum glutamic-oxaloacetic transaminase
IgA	Immunoglobulin A	SGPT₁	serum glutamic-pyruvic transaminase
IgB	Immunoglobulin B	soln	solution
IgG	Immunoglobulin G	TCD	tissue culture dose
IgM	Immunoglobulin M	TCD₅₀	median tissue culture dose
ILS	increased life span	tid	three times daily
im	intramuscular	UV	ultraviolet
ip	intraperitoneal	WBC	white blood cells (leukocytes)
IU	International Unit(s)	wk	week(s)
iv	intravenous	wt	weight
Km	Michaelis constant	X	times
LD	lethal dose	yr	year(s)
LD₅₀	median lethal dose		
M	molar		
μM	micromolar

- 79-5401 Assessment of Trichloroethylene as an Occupational Carcinogen. (Eng) Page, N. N. (Priorities and Res. Analysis Branch, National Inst. Occupational Safety and Health, 5600 Fishers Lane, Rockville, MD 20857). *IARC Sci Publ* (25): 75-79; 1979.

Decisions made by the National Institute for Occupational Safety and Health (NIOSH) regarding trichloroethylene (TCE) when it was found to be carcinogenic in mice are reviewed. The compound is used mainly in the vapor degreasing of metal parts, and it is estimated that over 100,000 workers (degreaser operators) are exposed to high levels of TCE. An additional 3.5 million workers are exposed to lower levels in other occupations. The carcinogenic effect may occur through a highly reactive epoxide which has a very short half life. There is a definite species difference in ability to metabolize TCE to the epoxide. Rats, which do not develop cancer after exposure to TCE, have a lower capacity for metabolizing the chemical to the epoxide. Epidemiological studies in Sweden on 750 workers exposed for more than 10 yr have not shown an increased risk for cancer, but this group is small statistically and the duration of exposure too short for ruling out carcinogenicity in humans. NIOSH has concluded that TCE is potentially carcinogenic in the workplace, but only weakly so. The present standard of 100 ppm in the US is considered to be too high, and a level of 25 ppm is recommended on the basis of the evidence available. (no refs)

- 79-5402 Food Additives, Drugs, and Pesticides. (Eng) Davis, W. (Research Training and Liaison Unit, International Agency Res. Cancer, 150 cours Albert Thomas, 69372 Lyon Cedex 2, France); Rosenfeld, C. *IARC Sci Publ* (25): 173-175; 1979.

A discussion of symposium papers dealing with the carcinogenic risks of food additives, drugs, and pesticides is summarized. Evidence was presented that compounds such as phenobarbital, which causes hepatic nodules in mice and rats, and 4,4'-dichlorodiphenyltrichloroethane, also carcinogenic in animals, may be noncarcinogenic in humans. Nevertheless, a very cautious approach has been assumed by agencies such as the US Occupational Safety and Health Administration, which proposes that positive animal data on carcinogenicity should supersede human data and that a significantly increased incidence of tumors in treated animals should be interpreted as evidence of carcinogenicity regardless of spontaneous cancer incidence. A number of agents cause hepatomas in mice, and the question has been raised as to whether these nodules are malignant or not. Regulations concerning risk-benefit of additives, drugs, and pesticides are not always consistent, and efforts are under way in the US and Europe to improve government regulation. (no refs)

- 79-5403 Carcinogenic Risk of Products Used in the Pharmaceutical and Related Industries. (Eng) Coustou, F. (Univ. Bordeaux II, Bordeaux, France). *IARC Sci Publ* (25): 129-149; 1979.

The problems, in France, of regulating drugs to eliminate or cur-

tail potential carcinogenicity are reviewed. Some carcinogens may be introduced during the manufacturing process, such as asbestos during filtration, vinyl chloride in aerosol production or packaging, or 2-naphthylamine and other aniline compounds during the dyeing process. The use of artificial sweeteners in the manufacture of foodstuffs is banned in France. At present, general regulations of the French government for the pharmaceutical industry state that agents should be tested for carcinogenicity prior to marketing only if: (1) the agent is closely analogous to known carcinogens or cocarcinogens; (2) a suspicion of carcinogenicity has been aroused during long-term toxicological testing; (3) the drug is to be administered over long periods of time. (22 refs)

- 79-5404 The Asbestos Industry and Statutory Control of its Hazards. (Eng) Newhouse, M. L. (IUC Centenary Occupational Health, London School Hygiene and Tropical Medicine, London, England). *IARC Sci Publ* (25): 59-70; 1979.

Data on the causal relationship between asbestos and respiratory disease, especially lung cancer, are reviewed. Pneumoconiosis related to asbestos exposure was reported in the 1920's, about 40 yr after the first asbestos factories were established in the United Kingdom and the US. The risk of lung cancer was first noted in the 1930's and established definitively by epidemiological studies in 1955 (the risk for exposed workers was nine times greater than that for the general population). An act regulating the asbestos industry was passed by the British Parliament in 1969. An advisory panel had found that bronchial carcinoma was a complication of asbestosis rather than of asbestos exposure, mesothelial tumors were linked to asbestos exposure, and crocidolite asbestos rather than chrysotile asbestos was the cause of the mesotheliomas. Beginning in 1971, clinical examinations were offered to all workers in the asbestos industry, and by 1974, nearly 7,000 workers had been examined. Three recent studies indicate that there may be a dose-response relationship between asbestos and lung cancer. On the basis of these studies, standards on asbestos exposure have been or are being revised. (11 refs)

- 79-5405 Role of Selenium in the Chemoprevention of Cancer. (Eng) Griffin, A. C. (Dept. Biochemistry, Univ. Texas System Cancer Center, M.D. Anderson Hosp. and Tumor Inst., Houston, TX). *Adv Cancer Res* 29: 419-442; 1979.

The role of selenium in the chemoprevention of cancer is reviewed. The topics included are the toxicology and pathology of Se, the nutritional aspects of Se (Se-responsive diseases, requirements for Se as a micronutrient, interactions of Se with other minerals in nutrition), Se as a causative factor or carcinogen in early reports, the lack of useful chemotherapeutic effects of Se on cancer growth, the effect of Se on carcinogenesis (inhibition of azo dye hepatocarcinogenesis), the biological functions of Se (as a cofactor for formate dehydrogenase, glycine reductase, and glutathione peroxidase), and the possible mechanisms of action of Se in the inhibition of carcinogenesis (decreasing the mutagenicity of various carcinogens, effects on carcinogen metabolism, protection of cells

against aberrant oxidative damage, and the stages of initiation or promotion of carcinogenesis affected by Se). (76 refs).

- 79-5406 Is Sodium Azide Preservative a Carcinogen (Letter to Editor)? (Eng) Liu, T. Z. (Center Advanced Medical Technology, San Francisco State Univ., San Francisco, CA 94132). *Clin Chem* 25(8): 1514-1515; 1979.

Sodium azide was a very potent mutagen in the Salmonella/microsome test system. Because there is a high (90%) correlation between carcinogenicity and mutagenicity in this system, sodium azide should be considered a potential carcinogen. (8 refs)

- 79-5407 Development, Growth Rate, Degree of Malignancy, and Chromosome Pattern of Morris Transplantable Hepatomas. (Eng) Morris, H. P. (Dept. Biochemistry, Howard Univ. Coll. Medicine, Washington, DC); Slaughter, L. J. *J Toxicol Environ Health* 5(2/3): 433-452; 1979.

A review is presented of the induction of Morris transplantable hepatomas in inbred Buffalo and ACI rats by various carcinogens, including N-2-fluorenyldiacetamide (2-FdiAA), N-2-fluorenylphthalamic acid (2-FPA), 2-(4'-methyl)benzoylamino fluorene, fluorenyl-2,7-disuccinamic acid, 2,4,6-trimethylaniline, 4'-fluoro-4-biphenylacetamide N-fluorenyl-2-nicotinamide, and aflatoxin B₁ (AFB₁). Growth, histology, and metastatic patterns of the tumor cell lines between 1973 and 1976 were investigated. Most of the tumors demonstrated a remarkably stable growth rate; some which had started slowly grew even more slowly in 1976, and some that had intermediate growth rates grew more slowly in 1973 than in 1976. The percentage distribution of six aneuploid hepatomas is presented. A haploid and a hyperdiploid line were the most homogeneous cell lines. The karyotype of each hepatoma line had a consistent number of abnormal chromosomes. Of the 48 tumor lines investigated, 31 demonstrated lung metastases in two transplant generations. Of 17 tumors induced by 2-FdiAA, 10 had lung metastases, 10/12 induced by 2-FPA had lung metastases, as did 3/5 induced by AFB₁. (25 refs)

- 79-5408 Environmental Chemical Carcinogens and Liver Cancer. (Eng) Linsell, C. A. (Interdisciplinary Programme and International Liaison Unit, International Agency Res. Cancer, Lyon, France). *J Toxicol Environ Health* 5(2/3): 173-181; 1979.

Chemical carcinogens that have been implicated in the etiology of human liver cancer are appraised. The liver carcinogens considered are those available to humans as contaminants of food and water or as additives. Naturally occurring liver carcinogens include mycotoxins [aflatoxins (AF's), cyclochlorotine, luteoskyrin, sterigmatocystin], pyrrolizidine alkaloids (isatidine, lasiocarpine, monocrotaline, and retrorsine), cycasin, safrole, and tannic acid. Synthetic liver carcinogens include nitrosamines and nitrosamides and chlorinated hydrocarbons (organochlorines, polychlorinated biphenyls, carbon tetrachloride, chloroform). The AF's are probably the most investigated group of chemical liver carcinogens. These compounds are among the most potent naturally occurring hepatocarcinogens. Considerable evidence has accumulated

relating their ingestion to human disease. Doses of a few parts per billion produce liver cancers in susceptible animals, and even single doses produce cancers in rats 1 yr after ingestion. However, there are marked differences among animal species, and continuous feeding for 6 yr is required to produce tumors in monkeys. Data from field studies in Mozambique, Thailand, Kenya, and Swaziland are summarized. AF intakes were recorded from food only; however, it was difficult to assess the intake of home-brewed beer made from cereals and of groundnuts, which are eaten irregularly as snacks. Therefore, the estimated intakes, which ranged from 3.5 nanograms (ng)/kg·day in Kenya to 222 ng/kg·day in Mozambique, must be considered as minimal. The crude liver cancer rate correlated with AF intake in the study areas. The association was observed in widely separated geographic areas, and no evidence of a contrary nature, ie, well-documented high levels of Af exposure paralleled by a low frequency of liver cancer, has been reported. - 79-5409 Chemistry of N-Nitrosamides and Related N-Nitrosamino Acids. (Eng) Chow, Y. L. (Dept. Chemistry, Simon Fraser Univ., Burnaby, British Columbia, Canada V5A 1S6). *ACS Symp Ser* (101): 13-37; 1979.

Differences in the reaction patterns of nitrosamides and nitrosamines when thermolyzed or photolyzed are discussed in relation to their ground state electronic configurations. At -150°C, a singlet excited state of a nitrosamide undergoes radiationless decay to afford a thermally unstable isomer that is readily dissociated by a second photon to the amidyl and nitric oxide radicals. Studies of nitrosamide photolysis by flash excitation provided kinetic rate constants of the resultant amidyl reactions, from which β -elimination was shown to arise from both the bimolecular reaction of the amidyl radical with the nitrosamide and a unimolecular elimination. (44 refs)

- 79-5410 N-Nitrosamines as Environmental Carcinogens. (Eng) Lijinsky, W. (Chemical Carcinogenesis Program, NCI Frederick Cancer Res. Center, Frederick, MD 21701). *ACS Symp Ser* (101): 165-173; 1979.

Investigations of the carcinogenic activity of N-nitrosamines are reviewed. Entirely different tumors are induced by these compounds in rats and in hamsters. The relative effectiveness of these compounds varies greatly, even between structurally closely related compounds. The relationship between human cancers and exposure to N-nitroso compounds has been difficult to establish. The major contribution to carcinogenic risk is probably through the in vivo formation of N-nitroso compounds by the reaction of amines with nitrite. The principal source of nitrite in the stomach is cured meats, and the rate of formation of N-nitroso compounds is proportional to the square of the nitrite concentration. The most favored site for the formation of carcinogenic N-nitroso compounds by reaction with secondary and tertiary amines is the stomach, with its acid conditions. Studies in which an amine and nitrite were fed simultaneously to laboratory animals are reviewed. Several of the amine-nitrite combinations formed carcinogenic N-nitroso derivatives, but others did not; however, these non-carcinogenic combinations cannot be considered definitive. Several of the amine-nitrite combinations that were negative in the rat test were positive in the Ames mutagenicity test, which is more sensitive than long-term animal bioassays. (31 refs)

- 79-5411 A Survey of Methods for the Determination of Non-volatile Nitrosamines in Foods. (Eng) Kubacki, S. J. (Dept. Instrumental Analysis, Inst. Fermentation Industry, ul. Rakowiecka 36, Warsaw, 12, Poland). *Pure Appl Chem* 51(6): 1369-1373; 1979.

Methods for determining total and individual nonvolatile nitrosamines in foods are reviewed. The most widely accepted method for estimating total nonvolatile nitrosamines is one that efficiently splits the N-NO group. The nitrite formed is determined after reaction with sulfanilamide and N-(1-naphthyl)ethylenediamine. Complete elimination of water from the reaction medium is essential. It is likely that the most profitable approach to determining individual nonvolatile nitrosamines is through the use of high-pressure liquid chromatography (HPLC). Coupling the thermal energy analyzer with HPLC allows the simultaneous determination of volatile and nonvolatile nitrosamines. (45 refs)

- 79-5412 Quantitative Aspects of Exposure and Mechanism in N-Nitrosamine Carcinogenesis. (Eng) Wishnok, J. S. (Dept. Nutrition and Food Science, Massachusetts Inst. Technology, Cambridge, MA 02138). *ACS Symp Ser* (101): 153-163; 1979.

Variations in carcinogenic potency of the N-nitrosodialkylamines (nitrosamines) are examined quantitatively both in terms of environmental exposure and formation and in the context of the mechanism through which nitrosamines initiate cancer. The relative risks of these compounds is discussed in terms of nitrosamines in cooked bacon. The typical range of concentration of nitrosamines in processed meats is 3-25 ppb for N-nitrosodimethylamine (NDMA), 2-12 ppb for N-nitrosodiethylamine (NDEA), and 5-50 ppb for N-nitrosopyrrolidine (NP). Relative potencies have been assigned to these compounds in BD rats: 7 for NDMA, 6 for NDEA, and 1 for NP. The structure-activity relationships of the nitrosamines were investigated. Computerized multiple regression analyses were performed on the acyclic nitrosamines, using $\log(1/D_{50})$ where D_{50} is the mean carcinogenic dose, as the dependent variable analogous to the relative biological response. It is shown that most of the variation in carcinogenicity within the series of acyclic nitrosamines can be associated with water-hexane partition coefficients and electronic inductive effects of substituents on the α -carbons. These methods may be useful in predicting carcinogenicity and as tools for probing mechanisms of carcinogenicity. (34 refs)

- 79-5413 N-Nitrosamines in Consumer Products and in the Workplace. (Eng) Krull, I. S. (New England Inst. Life Sciences, 115 Second Ave., Waltham, MA 02154); Edwards, G.; Wolf, M. H.; Fan, T. Y.; Fine, D. H. *ACS Symp Ser* (101): 175-194; 1979.

Data on the presence of N-nitroso derivatives in pharmaceuticals, commercial cutting fluids, cosmetics, skin lotions and shampoos, and herbicides are reviewed. Seventy-three prescription and over-the-counter drugs were analyzed by gas chromatography-thermal energy analysis and/or high-pressure liquid chromatography-thermal energy analysis. For most of the drug products, there does not appear to be a serious problem with regard to the presence of N-nitroso contaminants. Relatively high concentrations (0.02%-2.99%) of N-nitrosodiethanolamine (NDEIA) were found in com-

mercial cutting fluids. Since NDEIA causes cancer in two species of laboratory animals, cancer incidence among exposed workers should be studied. NDEIA levels in cosmetics ranged from trace amounts to 49,000 nanograms (ng)/g; in lotions, from 0 to 140 ng/g; and in shampoos from 0 to 260 ng/g. Further investigation is necessary to determine the exposure of beauty care and industrial workers to N-nitroso compounds via these products. In various herbicides, dimethylnitrosamine was present in concentrations ranging from 0 to 40 ppm, and dipropylnitrosamine was present at 0 to 195 ppm. Five out of six 2,4-dichlorophenoxyacetic acid herbicides contained DMN at levels between 250 and 650 μ g/liter. The results of thermoelectron analyses of various commercial products (pesticides, meat products, cosmetics, cutting fluids) are presented. The most frequently observed N-nitroso derivative was NDEIA. (64 refs)

- 79-5414 Tobacco Specific N-Nitrosamines: Occurrence, Carcinogenicity, and Metabolism. (Eng) Hecht, S. S. (Naylor Dana Inst. Disease Prevention, American Health Foundation, Valhalla, NY 10595); Chen, C. B.; McCoy, G. D.; Hoffmann, D. *ACS Symp Ser* (101): 125-152; 1979.

The relationship between tobacco-specific N-nitrosamines and the various cancers associated with tobacco usage, including cancer of the lung, oral cavity, esophagus, pancreas, and bladder, is reviewed. The major tobacco-specific nitrosamines derived from tobacco alkaloids include N'-nitrososornicotine (NNN) and 4-(N-methyl-N-nitrosamino)-1-(3-pyridyl)-1-butanone (NNK). Both compounds are found in relatively high concentrations in mainstream and sidestream tobacco smoke and in unburned processed tobacco. The major precursor for both compounds is nicotine. NNN induces esophageal and nasal cavity tumors in rats, tracheal tumors in hamsters, and lung adenomas in strain A mice. NNK is more tumorigenic than NNN in strain A mice. The activation pathway for NNN and nitrosopyrrolidine (NPY) may be metabolic α -hydroxylation, since electrophilic diazohydroxides and carbonium ions are generated upon decomposition of the unstable intermediates α -hydroxy-NPY, 2'-hydroxy-NNN, and 5'-hydroxy-NNN. In *Salmonella typhimurium*, the synthetic precursors to these intermediates, α -acetoxy-NPY, 2'-acetoxy-NNN, and 5'-acetoxy-NNN, were mutagenic without activation. After hydrolysis, the products of α -acetoxy compounds were all detected as metabolites of NNN and NPY. Products similar to those from α -hydroxylation of NNN were obtained from the metabolic α -hydroxylation of NNK. The role of these intermediates in carcinogenesis induced by NPY, NNN, and NNK is currently being studied. (56 refs)

- 79-5415 Gastric Cancer in Patients Who Have Taken Cimetidine (Letter to Editor). (Eng) Elder, J. B. (Dept. Surgery, Univ. Manchester, Royal Infirmary, Manchester M13 9WL, England); Ganguli, P. C.; Gillespie, I. E. *Lancet* 2(8136): 245; 1979.

Comments regarding an earlier article postulating a possible link between cimetidine (CM) therapy and gastric carcinoma are reviewed. It is not known whether CM is nitrosated in vivo, but the nitrosated compound derived from CM in vitro is analogous to N-methyl-N'-nitro-N-nitrosoguanidine. Also, the manufacturers have stated that CM can be nitrosated and that the nitrosocimetidine produced in vitro is mutagenic. Although early cancer research suggested that the period of latency between exposure to a potential carcinogen and the diagnosis of gastric car-

cinoma is several years, recent work with nitroso compounds in laboratory animals does not support the necessity of such a long latent period. Carcinomas can be readily produced in animals by the administration of nitroso compounds or their precursors in such tests. A recent publication reported a 5.36% incidence of gastric carcinoma in a group of patients after operations for duodenal ulcer, but not in unoperated patients. Any method used to reduce gastric acid secretion may increase the incidence of malignant change in the gastric mucosa. (24 refs)

- 79-5416 Gastric Cancer in Patients who Have Taken Cimetidine (2 Letters to Editor). (Eng) Mullen, P. W. (Dept. Pharmacology, Materia Medica and Therapeutics, Univ. Manchester, Stopford Building, Manchester M13 9PT, England); Guslandi, M. *Lancet* 1(8131): 1406; 1979.

Possible explanations for the development of gastric carcinoma in three previously reported patients who had taken cimetidine (CM) for dyspeptic symptoms are presented. A previous speculation on the existence of a carcinogenic N-nitroso derivative of CM in the stomach is unlikely. If the cancer was related to nitrosamines, their existence could have been due to the presence of salivary and gastric thiocyanate if the patients were smokers, to the consumption of thiocyanate- or nitrite-containing foods, or to the consumption of other drugs that can be nitrosated in acidic environments containing nitrite. In addition, if a connection between CM and gastric cancer is to be discussed, the effects of CM on gastric mucus glycoproteins should be borne in mind. (9 refs)

- 79-5417 Carcinogenicity of Lindane. (Eng) Reuber, M. D. (NCI Frederick Cancer Res. Center, Frederick, MD 21701). *Environ Res* 19(2): 460-481; 1979.

A review of every study on the carcinogenicity of lindane in animals was attempted. Lindane is highly carcinogenic in rats and mice. It induced benign and malignant neoplasms at all sites in male and female rats. Adrenal and pituitary carcinomas were increased markedly in male and female rats. Females were more susceptible than males. Ovarian carcinomas were increased in lindane-treated female rats. There were increased incidences of hepatic neoplasms in both sexes. Hepatic carcinomas were induced in four strains of mice. The incidence of hepatic neoplasms was markedly increased in CF1 strain mice. Rats (particularly males) given lindane also developed toxic lesions as a result of treatment. These lesions included interstitial fibrosis of the kidney and atrophy of the testes. They may have interfered with the development of neoplasms in male rats. (20 refs)

- 79-5418 Toluene. A Toxicologic Review. (Eng) Cohr, K. H. (Arbejdsmiljøinstituttet, Baunegardsvej 73, DK-2900 Hellerup, Denmark); Stokholm, J. *Scand J Work Environ Health* 5(2): 71-90; 1979.

The application, metabolism, toxicologic mechanisms, effects on specific organs, mutagenicity, carcinogenicity, biological indicators of exposure, and dose-response relationship of toluene are reviewed. In one study, the majority of 401 patients with lymphoid leukemia, bone marrow aplasia, myeloid leukemia, and myelofibrosis had been exposed to benzene and toluene. (150 refs)

- 79-5419 Time and Dose Factors in Carcinogenesis (Letter to Editor). (Eng) Brodsky, A. (P.O. Box 34471, W. Bethesda, MD 20034). *Health Phys* 36(3): 468-471; 1979.

The use of an analytical stochastic model for calculating and plotting graphs of the incidence of animals with tumors vs time is reported, and the results are compared with recently published results using an empirical lognormal model. For certain ranges of the parameters, the analytical model will also predict what appear to be lognormal curves of tumor probability vs time, similar to those plotted with the empirical model. However, the tumor incidence vs time curves with this model do not approximate lognormality. These curves are for situations in which the carcinogen is more rapidly removed from the animal's tissue, and thus there is no carcinogen present in later life to continue the first or second transitions toward the tumor state. The analytical model can also demonstrate lognormal-appearing graphs for a response vs dose curve, and it can also demonstrate the various shapes of the lognormal model that approximate linearity in some cases and S-shaped functions in other cases. The analytical model is not an empirical lognormal function but is, instead, an expression derived from integration from assumptions regarding the form of the probability of a first transition and the conditional probability of a second transition. Approx linear as well as S-shaped functions are consistent with the analytical model, depending on the particular carcinogen and its instantaneous probabilities and on whether the exposure is long-term or relatively acute. (6 refs)

- 79-5420 Carcinogenesis in Urogenital Sites. (Eng) Paulson, D. F. (Duke Univ. Medical Center, P.O. Box 2977, Durham, NC 27710). *Invest Urol* 16(2): 77-86; 1978.

An overview of carcinogenesis in urogenital sites is presented under the headings normal cellular control mechanisms, theories of carcinogenesis, chemical carcinogens, irradiation-induced carcinogenesis, viral carcinogenesis, viruses and human tumors, renal adenocarcinoma, and bladder and prostatic cancer. (128 refs)

- 79-5421 Changes in Mammalian Sperm Morphology after X-Ray and Chemical Exposures. (Eng) Wyrobek, A. J. (Biomedical Sciences Div., Lawrence Livermore Lab., Univ. California, Livermore, CA 94550). *Genetics* 92(Suppl, part 1): S105-S119; 1979.

Relevant concepts in studies of sperm morphology (SM), including morphological and genetic factors in sperm shaping and the effects of chemical and physical agents on SM, are reviewed. SM in mammals provides a unique approach to quantitating the effects of environmental agents on germ cells. In unperturbed male mice, the sperm of each genotype can be reproducibly characterized by the shape of the head, the overall percent of sperm with head-shape abnormalities, and the types of abnormalities seen. Genetic studies show that sperm shape is highly heritable and that the fraction of abnormal sperm is controlled by a multitude of autosomal factors plus, probably, involvement of the sex chromosomes. Exposure to ionizing radiation or to certain chemical agents in vivo leads to dosage-dependent increases in the fraction of sperm with head-shape abnormalities. These results are documented in numerous mammalian species, including humans. Evidence from mouse studies suggests that sperm shape is affected by mutagenic agents. Since sperm samples are easily obtained and SM can be rapidly quantitated, these observations suggest that SM in the mouse may

REVIEW

be an applicable screen for environmental effects on germ cells. Changes in sperm are also seen in the offspring of male mice exposed to radiation or chemical alkylating agents. Preliminary evidence suggests that these changes represent heritable sperm shape abnormalities that can be further transmitted to subsequent generations. The problems of determining the genetic implications of induced sperm abnormalities in exposed males are discussed. SM testing may have a direct application to humans. (63 refs)

- 79-5422 Carcinogen Prediction in the Laboratory: A Personal View. (Eng) Garner, R. C. (Cancer Res. Unit, Univ. York, Heslington, York YO1 5DD, England). *Proc R Soc Lond [Biol]* 205(1158): 121-134; 1979.

Short-term chemical carcinogenicity tests based on the hypothesis that all carcinogenic chemicals are electrophiles or must be metabolically converted to electrophiles are reviewed and compared with traditional methods. In vitro tests include nucleic acid reactions (for detection of electrophilic metabolites) in prokaryotes or in eukaryotes and sebaceous gland suppression or nonspecific esterase activity in sebaceous glands of mouse skin (for polycyclic hydrocarbons only). In vivo tests include the use of strain A mice for scoring lung adenomas, scoring the numbers of transformed cells taken from hamster fetuses after carcinogen administration to the mother, culture and examination of organs taken from treated animals, and the use of density gradient centrifugation to detect DNA damage in vivo. Compared with long-term animal studies, these short-term tests should enable large numbers of chemicals to be screened rapidly and inexpensively. (56 refs)

- 79-5423 Possibilities and Limits of the Ames Test. (Ger) Dehnen, W. (No affiliation given). *Lufthyg Silikoseforsch* 11: 81-87; 1978.

The possibilities and limitations of the mutagenicity and carcinogenicity testing of chemicals in the Ames Salmonella mutagenicity assay are weighed. The test is simple, rapid, and inexpensive. However, the result cannot be freely extrapolated to in vivo conditions. It is only with some reservations that carcinogenicity can be inferred from the mutagenicity found in the assay, because about 90% of all substances tested are both mutagenic and carcinogenic; a negative response does not rule out the carcinogenicity of a given substance. Also, there is no definite correlation between the intensity of the two effects. (14 refs)

- 79-5424 Bacterial Tests for Potential Carcinogens. (Eng) Devoret, R. (No affiliation given.). *Sci Am* 241(2): 40-49; 1979.

New short-term bacterial tests, including the Ames test, the inductest, and the lambda mutatest, for identifying environmental agents that cause DNA damage and for clarifying the mechanism of DNA damage are described. Induction of a dormant bacterial virus, prophage lambda, is detected in the inductest. In the mutatest, a modified form of the prophage makes plaques on a lawn of *Escherichia coli* when it undergoes mutation. The enzyme-induction test is a biochemical counterpart of the inductest. - 79-5425 'Human' and 'Animal' Carcinogens. (Eng) Teichmann, B. (Dept. Chemical Carcinogenesis, Central Inst. Cancer Res., Acad. Sciences GDR, Lindenberger Weg 80, 1115 Berlin-Buch, E. Germany); Schramm, T. *IARC Sci Publ* (25): 203-206; 1979.

The terms human carcinogen and animal carcinogen are discussed in relation to cancer research, prevention, and control legislation. A chemical demonstrated to be carcinogenic in animals should be considered to represent a risk to humans. However, nonexperts tend to consider that animal carcinogens produce cancer only in animals and can be neglected with regard to the human situation. These terms should either be avoided or used only in the context of generally accepted and available definitions. (9 refs)

Information concerning the pathogenesis, detection, and management of drug- and chemical-induced hepatotoxicity is reviewed. Tables listing chemicals carcinogenic in humans and possible and actual occupational hepatotoxins are given. (24 refs)

- 79-5427 Residues of Carcinogenic Animal Drugs in Food: Difficulties in Evaluation of Human Safety. (Eng) Somogyi, A. (Dept. Drugs, Animal Nutrition and Residue Res., Federal Office Health, Thiel-allee 88-92, 1000 Berlin 33, W. Germany). *IARC Sci Publ* (25): 123-127; 1979.

Permissible levels of potentially carcinogenic drug residues in animals destined for human consumption are reviewed. The appearance of new analytical methods with high sensitivity and specificity permits the detection of residues at the parts/billion level. The parts/trillion level may soon be reached. There are scientists who argue the case for zero tolerance for carcinogens in food. It is suggested, however, that the relative carcinogenic risk of consuming animals with drug residues should be compared with that of smoking a single cigarette or eating a charcoal-broiled steak. The benefits presently gained from drugs that cure and prevent infections and parasitic diseases in food-producing animals should make the presence of very low levels of these drugs or their metabolites in the human diet acceptable. (no refs)

- 79-5428 Decision on the Control of a Dietary Carcinogen-Aflatoxin. (Eng) Linsell, C. A. (International Agency Res. Cancer, 150 cours Albert Thomas, 69372 Lyon Cedex 2, France). *IARC Sci Publ* (25): 111-122; 1979.

The discovery of aflatoxin as a carcinogen is reviewed. Suspicions were first aroused when poultry and fish fed mold-contaminated peanuts and/or feeds developed turkey "X" disease and liver cancer, respectively. Laboratory investigations of the carcinogenicity of aflatoxins were carried out in a wide range of animals, and marked differences in species susceptibility were noted. Field studies in Africa and Asia showed a significant correlation between estimated av daily adult intake of aflatoxin and the incidence of liver cancer. The staple foods of most of the

developing countries are at risk for aflatoxin contamination, as are many of their exports to developed countries. Peanuts, used for human and animal consumption, are particularly at risk. Permissible limits for aflatoxin contamination of foodstuffs of 21 countries are tabulated, along with permissible limits set by the Council of the European Economic Community for aflatoxin B₁ in animal feed. Regulatory actions on aflatoxins taken by industrialized countries do not protect the food supplies of indigenous populations of countries producing crops most likely to become contaminated because of a conducive climate. - 79-5429 The Approach of the European Communities to the Assessment of the Carcinogenic Risk of Environmental Chemicals, in Particular, Artificial Colourings. (Eng) Bourdeau, P. (Directorate General Res., Science and Education, Commission European Communities, 200 rue de la Loi, 1040 Brussels, Belgium); Ott, H.; Haigh, R. *IARC Sci Publ* (25): 101-109; 1979.

A brief outline is given of the rationale of the Environmental Research Program of the European Economic Community (EEC) and of its implementation. The major part of the program is devoted to research on the exposure-effect relationships for mutagens and carcinogens and to the establishment of criteria. As a first step, a battery of test systems for mutagenicity screening is being established. These will be evaluated in a comparative test program. In a discussion of EEC legislative actions on food colorings, the criteria used by the Scientific Committee for Food to classify and evaluate coloring agents are listed. Proposed regulatory action includes the classification of agents as unacceptable, temporarily acceptable, and acceptable. (no refs)

- 79-5430 Extraction of Trace Amounts of Organic Compounds from Water with Porous Organic Polymers. (Eng) Dressler, M. (Inst. Analytical Chemistry, Czechoslovak Acad. Sciences, 611 42 Brno, Czechoslovakia). *J Chromatogr* 165(2): 167-206; 1979.

A concentration technique for analyzing low concentrations of organic water pollutants is described. The technique is based on the sorption of organic compounds on organic porous polymers. The principles of the method, the characteristics and applications of various types of sorbents, the quality requirements for the materials used, and the sensitivity of the method are discussed. - 79-5431 Scientific Bases for Identification of Potential Carcinogens and Estimation of Risks. Report of the Interagency Regulatory Liaison Group, Work Group on Risk Assessment. (Eng) U.S. Environmental Protection Agency (Interagency Regulatory Liaison Group, Room 500, 1111 18th Street, N.W., Washington, DC 20207). *J Natl Cancer Inst* 63(1): 241-268; 1979.

A description is given of (1) the basis for the qualitative evaluation of a particular substance for potential carcinogenicity and how the results of epidemiological studies and animal bioassays, along with other types of information, are used in making that evaluation; and (2) methods used for quantitative estimates of the carcinogenic risk posed by the substance, if these risk estimates are required. Three types of evidence can be used to identify potential car-

cinogens: (1) epidemiologic evidence from studies of exposed human populations, (2) experimental evidence from long-term bioassays on animals, and (3) supportive or suggestive evidence from studies of chemical structure or from short-term or other tests known to correlate with carcinogenicity. Scientific bases for accepting evidence from these three sources are delineated, along with factors that should be considered in evaluating experimental and epidemiologic data. The experimental design and conduct of animal studies influence the evaluation of these studies. Ways of evaluating data from experimental animal studies of widely varying content and quality for purposes of identifying carcinogens are presented. Certain carcinogenic responses observed in experimental animals may not be predictive of human response. Current methodologies for the quantification of risk are described. There are mathematical models that can extrapolate, within a biologic system, cancer incidence data observed at experimental dose levels to estimate risks at the (usually much lower) levels that are of concern for humans. Factors that should be considered in attempts to identify the human population(s) at risk and to define their conditions and levels of carcinogen exposure are also presented. Possible methods of correlating the magnitude of effects observed in one human population or in experimental animals with the magnitude of effects in the human population for which the estimate of risk is being made are given. Limitations in current risk estimation methodologies are described, as are the problems of ensuring that human risk is not underestimated. Finally, the issue of thresholds for carcinogens is reviewed. (127 refs)

- 79-5432 Review of Pesticide Carcinogenesis Data and Regulatory Approaches. (Eng) Saffiotti, U. (Experimental Pathology Branch, Div. Cancer Cause and Prevention, NCI, Bethesda, MD). *IARC Sci Publ* (25): 151-166; 1979.

Carcinogenicity data are presented for 47 pesticides evaluated in the IARC Monograph series. These pesticides have been both poorly and scantily tested for carcinogenicity. Additional tests have been carried out under the NCI Carcinogenesis Program, and detailed results of the bioassays are published in the NCI Carcinogenesis Technical Report Series. Preliminary reports are published in the Federal Register. In a review of regulatory approaches to pesticides, international activities are outlined and examples are given of factors, such as public concern, scientific work, and governmental response, contributing to the development of such regulations. The problem of risk assessment has been approached from many sides, but it remains largely unsolved. Besides risks and benefits, an essential component in evaluation is the analysis of technological alternatives. Two other factors are public documentation of the process of evaluation and registration of environmental carcinogens and their uses. Reduction of exposure to environmental carcinogens to a minimum feasible level depends on social, economic, and temporal factors and implies the acceptance of a finite level of risk. (36 refs)

- 79-5433 Epidemics of Non-Infectious Disease. (Eng) Lawther, P. J. (MRC Toxicology Unit, Clinical Section, St. Bartholomew's Hosp. Medical Coll., Charterhouse Square, London EC1M 6BQ, England). *Proc R Soc Lond [Biol]* 205(1158): 63-75; 1979.

Noninfectious diseases that have been associated with exposure to carbon tetrachloride, polycyclic aromatic hydrocarbons, asbestos, mercury, and dioxin are reviewed. 1,2,5,6-Dibenzanthracene and 3,4-benzpyrene were the first known carcinogenic hydrocarbons;

REVIEW

these and other polycyclic aromatic hydrocarbons have been associated with skin and lung cancers. Carcinoma of the bronchus and pleural and peritoneal mesotheliomata have been associated with asbestos exposure, and cigarette smoking has been shown to be a synergistic factor. An increase in liver tumors has been reported in Vietnam and is thought to be related to dioxin exposure. (47 refs)

- 79-5434 Carcinogenicity of Endrin. (Eng) Reuber, M. D. (NCI Frederick Cancer Res. Center, Frederick, MD 21701). *Sci Total Environ* 12(2): 101-135; 1979.

The carcinogenicity of the chlorinated hydrocarbon insecticide endrin is reviewed. Endrin is carcinogenic for rats and, most likely, mice and dogs. When fed in the diet, it caused significant incidences of malignant neoplasms at all sites. In one study, female rats were susceptible to the development of neoplasms of the endocrine organs, particularly carcinomas of the adrenal and pituitary glands, as well as neoplasms of the reproductive system. In other studies, female rats tended to have carcinomas of the endocrine system, mammary gland, and reproductive system, and males and females tended to have lymphomas. Rats developed unusual malignant neoplasms, such as Kupffer cell sarcomas of the liver and sarcomas of the mammary gland, uterus, and stomach. There also were toxic changes, particularly in male rats. These lesions included interstitial fibrosis of the kidney; polyarteritis of the mesenteric, pancreatic, and other arteries; and atrophy of the testes. Such lesions generally interfered with the health of the rats and with the development of neoplasms. Dogs receiving endrin for 2 yr had bone marrow hyperplasia (HP), lesions of the thyroid gland, and lesions of the skeletal muscle. They also had mild or diffuse HP of the liver; mild atrophy of the testes; focal HP of the prostate gland; HP, adenoma, or carcinoma of the parathyroid gland; and occasional fibrosis of the spleen. One female dog had an early carcinoma of the thyroid gland. Mice ingesting endrin developed increased incidences of carcinoma of the liver and sarcoma of the uterus. (29 refs)

- 79-5435 Studies of Reserpine and Breast Cancer in Rochester, Minnesota. (Eng) Labarthe, D. R. (Dept. Medical Statistics and Epidemiology, Mayo Clinic, Rochester, MN); O'Fallon, W. M. In: *Epidemiological Issues in Reported Drug-induced Illnesses - S.M.O.N. and Other Examples*. Proceedings of an international symposium held 19-21 January 1976, Honolulu, HI. Gent, M.; Shigematsu, I., eds. (Hamilton, Canada: McMaster University Library Press): 337 pp.: 91-98; 1978.

Two studies of reserpine and breast cancer, both based on the medical record linkage system for the population of Rochester, Minnesota, are reviewed. Neither the retrospective case-control study nor the prospective cohort study of hypertensive women supports the hypothesis of an association between reserpine use and breast cancer. The fundamental methodological features of these studies are described in relation to definition of the agent and illness in question, the selection of subjects for study, and the ascertainment of exposure to the agent and the occurrence of disease. A conceptual scheme is suggested for considering successive stages of the scientific and policy issues involved, and the fundamental importance of the methodological issues is emphasized. (12 refs)

- 79-5436 Drug-induced Chronic Hepatic Disease. (Eng) Zimmerman, H. J. (Veterans Admin. Medical Center, 50

Irving St., N.W., Washington, DC 20422). *Med Clin North Am* 63(3): 567-582; 1979.

The induction of chronic active hepatitis, subacute hepatic necrosis, steatosis, phospholipidosis, vascular hepatic lesions, hepatic granulomas, cirrhosis, noncirrhotic portal hypertension, and neoplasms by various drugs is reviewed. The relationships between liver adenoma or carcinoma and oral contraceptives and between hepatic angiosarcoma and vinyl chloride or thorium dioxide exposure are discussed. (75 refs)

- 79-5437 Congenital Malformations and Other Reproductive Hazards from Environmental Chemicals. (Eng) Sullivan, F. M. (Dept. Pharmacology, Guy's Hosp. Medical Sch., St. Thomas St., London SE1 9RT, England); Barlow, S. M. *Proc R Soc Lond [Biol]* 205(1158): 91-110; 1979.

Possible adverse effects of chemical exposure on reproduction are discussed, and data concerning the reproductive outcome after exposure to chemicals in the workplace or environment are reviewed. Exposure of men to environmental chemicals may lead to cancer in their offspring; a study of 386 children dying from malignant disease before 5 yr of age showed a significant excess of fathers in hydrocarbon-related occupations. The association between vaginal cancer and prenatal diethylstilbestrol exposure has been established. Angiosarcomas have been reported in offspring of pregnant rats exposed to vinyl chloride monomer. Other possible transplacental carcinogens include anesthetics and irradiation. (103 refs)

- 79-5438 Mechanism of Action of Estrogen Antagonist: Relationship to Estrogen Receptor Binding and Hyperestrogenization. (Eng) Clark, J. H. (Dept. Cell Biology, Baylor Coll. Medicine, Houston, TX 77030); Hardin, J. W.; McCormack, S. A.; Padykula, H. A. *Prog Cancer Res Ther* 10: 107-133; 1978.

The relationship of estrogen receptor binding and hyperestrogenization to the mechanism of action of estrogen antagonists is reviewed, and a new classification is proposed for estrogen agonists and antagonists. Estriol is a short-acting estrogen and, hence, acts as a partial agonist-antagonist when injected. However, when it is implanted, it acts as an agonist with no antagonistic properties. Thus, estriol, along with dimethylstilbestrol, mesobutoestrol, and 16-oxoestradiol, are classified as short-acting estrogens. The long-acting estrogens are divided into two classes, A and B, according to their retention times in the body. Subclass A includes estradiol and diethylstilbestrol (DES), because both of these hormones are fully agonistic, with no antagonistic properties, and they have similar nuclear retention times and biologic potencies. Subclass B includes nonsteroidal estrogen antagonists such as Nafoxidine, CI-628, and Clomid, because of their ability to stimulate estrogenic function over longer periods of time than estradiol or DES and yet manifest antagonistic properties when given as multiple injections. (50 refs)

- 79-5439 Oestrogen Replacement Therapy (2 Letters to Editor). (Eng) Greenblatt, R. B. (Medical Coll. Georgia, Augusta, GA 30901); Gambrell, R. D.; Sturdee, D. W. *Lancet* 1(8131): 1398-1399; 1979.

Two letters point out that an editorial concerning the risk of endometrial cancer in patients on hormone-replacement therapy fails to mention recent reports claiming that the addition of cyclic courses of a progestagen at monthly intervals reduces the incidence of endometrial cancer. (19 refs)

- 79-5440 Tumorigenic Aspects. (Eng) Kirk, M. E. (Dept. Pathology, Montreal General Hosp., 1650 Cedar Ave., Montreal, Canada H3G 1A4). *Int J Gynaecol Obstet* 16(6): 473-478; 1979.

Tumors (except those of the pituitary) that have been reported to occur in women taking combined oral contraceptive (OC) preparations are reviewed. Tumors of the cervix (dysplasia and its progression to carcinoma in situ), liver (focal nodular hyperplasia and liver cell adenomas), and breast (fibroadenoma, fibrocystic disease, and carcinoma) are considered with respect to pathologic features, both gross and microscopic, and differential diagnosis. The principal focus of the review is on the liver. There is a bewildering array of hepatic lesions, with considerable problems of nomenclature and pathogenesis, but it is likely that only two pathologically distinct lesions occur: focal nodular hyperplasia (FNH) and liver cell adenoma (LCA). FNH has been well-described, but its etiology and pathogenesis remain undetermined. LCA has also been well-described and, although its etiology remains undetermined, there is general agreement that it is a benign neoplasm. It is premature to draw conclusions about a relationship between OC's and liver tumors. Although the endocervical mucosa is very responsive to hormones and many women who use OC's have a reversible hyperplasia of the endocervical epithelium, the effects of OC's on the cervix cannot be fully evaluated until further prospective studies are carried out. The same breast diseases occur regularly in both users and nonusers of contraceptive hormones. The findings of several large studies have so far refuted any relationship between breast disease and OC use. Because many carcinogens have a lengthy latency period, final conclusions must await longer-term, more well-designed studies. (33 refs)

- 79-5441 Serious Adverse Reactions to Oral Contraceptives. (Eng) Mann, J. I. (Dept. Social Medicine, Oxford Univ., 8 Keble Rd., Oxford OX1 3QN, England). In: *Epidemiological Issues in Reported Drug-induced Illnesses - S.M.O.N. and Other Examples*. Gent, M., Shigematsu, I., eds. (Hamilton, Ontario: McMaster University Library Press) 337 pp.: 59-68; 1978.

Studies that suggest an association between oral contraceptive (OC) use and fatal adverse reactions to these preparations are summarized. A comparison between fatality rate resulting from their use and mortality from complications of unwanted pregnancies in women using a less effective method of contraception (diaphragm) suggests that fatal adverse reactions to OC's account for a greater number of deaths. Forty-six cases of benign liver adenoma and one case each of hepatocellular carcinoma and hepatoblastoma have been described in women using OC's. An increased risk of breast cancer has been described in a case-control study of certain high-risk users. (18 refs)

- 79-5442 Oral Contraceptives and Neoplasia. (Eng) Huggins, G. R. (Dept. Obstetrics and Gynecology, Hosp. Univ.

Pennsylvania, 3400 Spruce St., Philadelphia, PA 19104); Giuntoli, R. L. *Fertil Steril* 32(1): 1-23; 1979.

Available data regarding possible associations between oral contraceptives (OC) and human neoplasia are reviewed in light of the pregnancy risk or benefit of oral contraception. The principal investigative methods in the human are: case reports; disease rates and trends; case-comparison (retrospective) studies; and cohort (prospective) studies. These methods cannot prove a causal relationship between exposure to a possible carcinogen and the occurrence of disease. Both the progestogen-only and the combined OC's protect against the development of benign breast disease, and there is no apparent association between OC use and the development of breast carcinoma. Long-term combined OC use appears to be related to the development of benign liver neoplasia, the risk increasing with steroid dose and age of the user. Long-term postmenopausal use of estrogens, but not progestogen-only or combined OC's, significantly increases the risk of developing endometrial hyperplasia and endometrial adenocarcinoma. The use of low-dose combined OC's does not appear to significantly increase the risk of leiomyoma, and there is no apparent increased risk of developing cervical dysplasia or carcinoma in situ among low-risk patients using low-dose combined OC's. High-risk patients taking high-dose OC's may be at increased risk for development of cervical dysplasia or progression to carcinoma in situ. Data are insufficient to establish any association between OC use and pituitary neoplasia, but OC's may have an adverse association with resolution of hydatidiform moles. (196 refs)

- 79-5443 Gastrointestinal Side Effects of Oral Contraceptives. (Ger) Braendli, B. (Gastroenterologische Abteilung Medizinische Klinik, Kantonsspital, CH-6004 Lucerne, Switzerland); Filippini, L. *Med Klin* 74(12): 425-436; 1979.

The use of oral contraceptives (OC) is associated with an increased incidence of liver neoplasms, usually benign. The most frequently occurring neoplasms have been termed liver cell adenoma, benign hepatoma, or focal nodular hyperplasia (FNH). Two recent studies differentiate between liver adenoma and FNH on pathological and angiographic grounds, and they state that the incidence of FNH is not related to use of OC. (157 refs)

- 79-5444 The Effects of Radiation on the Chromosomes of Patients Susceptible to Cancer. (Eng) Harnden, D. G. (Dept. Cancer Studies, Univ. Birmingham Medical Sch., Birmingham B15 2TJ, England); Taylor, A. M. In: *Mutagen-induced Chromosome Damage in Man. Proceedings of a Symposium held in Edinburgh, Scotland, July 7-8, 1977*. Medical Research Council (Edinburgh, Scotland): 355 pp.: 52-61; 1978.

Evidence of radiosensitivity in patients with three genetically determined diseases, ataxia telangiectasia (AT), retinoblastoma, and basal cell nevus syndrome (BCNS), is reviewed. All three diseases are associated with an increased incidence of malignant disease, and the radiosensitivity may be directly linked to the primary susceptibility to cancer. The literature contains three case reports of AT patients with unusual radiosensitivity and several reports of severe responses to radiation therapy in BCNS patients. In addition, the osteosarcomas sometimes associated with retinoblastomas may be evidence of radiation sensitivity. A study of radiosensitivity at the cellular level showed a reduced survival of fibroblasts from AT patients when they were exposed to radiation. A recent report indicated an unusual radiosensitivity of cells from

a patient with retinoblastoma and an interstitial deletion of a chromosome 13 (most retinoblastoma patients have normal chromosomes). Cells from patients with BCNS display normal sensitivity to cell killing after exposure to γ -rays. Evidence of radiosensitivity at the chromosome level has been found only for AT, and various possible mechanisms leading to these chromosome aberrations are suggested. There is no definitive evidence that the radiosensitivity to chromosome damage in AT patients is linked to the observed spontaneous chromosome damage and clone formation or that the clones are in some way linked to a predisposition to lymphoid neoplasms. (47 refs)

- 79-5445 Regulation of Radiation Pollution: Its Possible Usefulness in Strategy for Intervention Against Chemical Mutagens. (Eng) Latarjet, R. (Section de Biologie, Institut Curie, 26 rue d'Ulm, 75231 Paris Cedex 5, France). *IARC Sci Publ* (25): 207-228; 1979.

The history of the regulation of radiation to limit human exposure is traced from the 1952 Conference on Radiobiology and Radiation Protection held in Stockholm to the present (1977). The present permissible radiation doses recommended by the International Commission for Radiation Protection (ICRP) are critically evaluated. The question is then raised as to whether the large volume of research in the field of radiation can serve as an example in regulation of chemicals. A system of rad-equivalences equating the biological effect of a 'dose' of a harmful chemical with that of a 'dose' of radiation is described. Once the equivalence is established experimentally, regulations concerning radiation safety can be extrapolated to apply to a given compound. The use of a common unit, the rad, would allow the summing of risks from several mutagens in order to determine a possible additive effect. Conditions necessary for establishing rad-equivalence are outlined; and ethylene, formaldehyde, and benzo(a)pyrene are given as examples. The limitations of the equivalence system are discussed; eg, each chemical may affect the DNA in a unique way to cause mutational changes. (29 refs)

- 79-5446 Aging, Environmental Influences, and Photocarcinogenesis. (Eng) Forbes, P. D. (Center Photobiology, Temple Univ. Sch. Medicine, Philadelphia, PA 19140); Davies, R. E.; Urbach, F. *J Invest Dermatol* 73(1): 131-134; 1979.

Current understanding of aging, environmental influences, and photocarcinogenesis is reviewed. Many studies have provided evidence for the significance of light energy in the etiology of basal and squamous cell carcinomas. The induction of malignant melanoma may depend on the interaction of sunlight with other, as yet unidentified, factors. Several models for estimating the photobiological impact of the reduced ozone layer have been proposed. Because some of the variables in these models cannot be resolved with data from humans, the calculations must be based on studies of laboratory animals. Preliminary observations from such experiments and from limited clinical data suggest that the tumor response reflects two aspects of aging: the passage of time required by repeated exposure that results in accumulated damage and the biological effect correlated with time passage, ie, physiological age. The mechanism by which physiological age influences photocarcinogenesis is not clear. It may be based on a structural change (eg, thickening of the protective stratum corneum), a change in the biological properties of the organism (eg, a reduction in the DNA repair capacity or an alteration in the

fibrous protein), or any of the other phenomena currently associated with aging. (23 refs)

- 79-5447 Photochemotherapy in Psoriasis: A Review. (Eng) Vella Briffa, D. (Inst. Dermatology, St. John's Hosp. Diseases Skin, Homerton Grove, London E9 6BX, England); Warin, A. P. *J R Soc Med* 72(6): 440-446; 1979.

The use of photochemotherapy for psoriasis may be mutagenic or carcinogenic. In the presence of long-wave UV irradiation (UVA), psoralens produce mutagenic effects in various biological systems, and the ip or topical administration of 8-methoxypsoralen (8-MOP) followed by UVA exposure has been shown to initiate skin tumor formation in rodents. The only published evidence for the carcinogenicity of 8-MOP and UVA in humans comes from experiences with four xeroderma pigmentosum patients and one patient with vitiligo and a history of arsenic ingestion who developed multiple skin cancers within months of starting photochemotherapy. (94 refs)

- 79-5448 DNA Repair Processes Protect Human Beings from Premature Solar Skin Damage: Evidence from Studies on Xeroderma Pigmentosum. (Eng) Robbins, J. H. (NIH, Building 10, Room 12N238, Bethesda, MD 20014); Moshell, A. N. *J Invest Dermatol* 73(1): 102-107; 1979.

Studies of xeroderma pigmentosum (XP) are reviewed to elucidate mechanisms resulting in solar damage in normal persons. Histologically, hyperpigmented macules in XP patients, which occur on sun-damaged skin, may represent the spectrum of sunlight-induced melanocytic changes that can progress to malignant melanoma. Studies of defective UV light (UVL)-induced unscheduled DNA synthesis in XP cells, particularly in cell-fusion experiments, have been useful in the classification of XP patients into complementation groups. The atrophy of sun-exposed XP epidermis might reflect cellular sensitivity to the killing effects of UVL demonstrated in vitro. Fibroblasts from XP patients have a higher frequency per unit of UVL than normal fibroblasts. Such increased mutability of XP cells might be the basis for several of the clinical findings in the sun-exposed skin of XP patients. Mutation of dermal fibroblasts might result in abnormal metabolic processes that, perhaps, account in part for the basophilic degeneration of the collagen and for solar elastosis. (58 refs)

- 79-5449 Radiation-induced Sarcomas of Bone. (Eng) Brady, L. W. (Dept. Radiation Therapy and Nuclear Medicine, Hahnemann Medical Coll. and Hosp., 230 N. Broad St., Philadelphia, PA 19102). *Skeletal Radiol* 4(2): 72-78; 1979.

Data on radiation-induced bone sarcomas, the frequency of which is low, are reviewed. The radiobiologic effect of x- or γ -radiation is mostly determined by the magnitude of the absorbed dose and its distribution within the tissues. The wide variation in absorbed dose is most dramatic in patients treated with photon energies <500 kilovolts. There is wide disparity in absorbed dose between soft tissues and the immediately adjacent bone tissues. The more superficial portions of bone have higher dose distributions than the deeper surfaces. Most experiments on the production of tumors by irradiation have been concerned with carcinomas and superficial sarcomas. In humans, radiation osteitis is present in about 50% of the cases. The histologic features of bone tumors range from

osteogenic sarcomas in 50%-60% of the cases to fibrosarcomas, chondrosarcomas, aplastic spindle cell sarcomas, and giant cell carcinomas. The median latent period is 11 yr, and animal studies show that this period is inversely related to radiation dose. The radiobiologic mechanism in carcinogenesis at the dose level used in definitive radiotherapy is thought to be at least a product of two processes of cell kill probabilities and transformation rate. Cancerocidal levels leave fewer reproductively capable cells to proliferate in a transformed state. The literature shows that no radiation-induced sarcomas were seen at doses <3,000 rads given in 3 wk. Sensitivity to radiation carcinogenesis is thought to be related to the age of the patient. The induction of malignant bone tumors is so serious a late effect of radiation therapy that an estimate of the magnitude of the risk is important. With the changing contemporary management of malignant disease and with increasing numbers of patients being treated with combined radiation therapy and multiple drug chemotherapy, there may be an associated shortening of the cancer induction period and an increase in the frequency of second malignant lesions or neoplasms. Criteria for the diagnosis of radiation-induced bone sarcomas are presented. (53 refs)

- 79-5450 Evaluation of the Risks of Somatic Radiation and Recommendations of ICRP Publication No. 26 (1977). (Ger) Schmitz-Feuerhake, I. (Fachbereich Physik, Universität Bremen, Bibliothekstrasse, 2800 Bremen 33, W. Germany) Batjer, K.; Muschol, E. *ROEFO* 131(1): 84-89; 1979.

Data from several epidemiological studies of cancer incidence in population groups exposed to low levels of radiation were analyzed, as were the assumptions and calculations used to prepare the International Commission on Radiological Protection (ICRP) report No. 26. Data on cancer incidence among persons exposed to atomic bomb explosions, patients given radiation for benign conditions (spondylitis, tinea capitis), persons receiving above-average levels of natural radiation (eg, living at high elevations and along lines of geomagnetic flux), radiologists, and plutonium workers were analyzed to estimate cancer risk. The results showed that the risks from small doses of radiation were underestimated by a factor of approx 3 in the ICRP report. (64 refs)

- 79-5451 Is Ultrasonic Therapy Carcinogenic? (Eng) Wheeler, R. H. (Dept. Environmental, Public, and Occupational Health, American Medical Assoc., Chicago, IL). *JAMA* 242(2): 192; 1979.

Although ultrasound causes cavitation of cellular fluid, disruption in DNA strands, and acoustic microstreaming, there is no evidence that either acute or chronic ultrasonic radiation exposure induces tumors. (1 ref)

- 79-5452 Health Implications of Nuclear Energy (2 Letters to Editor). (Eng) Drum, D. E. (Harvard Medical Sch., Boston, MA 02115); Joseph, P. G. *Ann Intern Med* 91(1): 127-128; 1979.

A recent editorial on the potential health hazards of nuclear energy is discussed. It is stated on the one hand that there are no examples of known genetic effects caused by low-level (less than 5 roentgen-equivalents-man/yr) radiation in humans and that it has not been

proven that plutonium or spent fuel can cause high incidences of both prompt and latent cancer deaths. In contrast, strong support for the conclusion that nuclear energy poses significant health hazards is offered. (10 refs)

- 79-5453 Radioactivity in Nonuranium Mines and Its Effects on the Health of the Miners. (Rum) Mihail, G. (Institutul de igiena si sanatate publica, Iasi, Romania); Gradinaru, M.; Weissbuch, H. *Rev Ig [Bacteriol]* 27(4): 289-294; 1978.

The general occupational hygienic aspects of radiation from ^{222}Rn , ^{210}Pb , and ^{210}Po in nonuranium mines are reviewed. The carcinogenic effect of radiation can be enhanced by dust-induced lesions in the bronchial epithelium. (28 refs)

- 79-5454 The Specter of Malignancy and Criteria for Cell Lines as Substrates for Vaccines. (Eng) Salk, J. (Salk Inst. Biological Studies, P.O. Box 1809, San Diego, CA 92112). *Adv Exp Med Biol* 118: 107-113; 1979.

The factor limiting the acceptance of infinite life-span cell lines for vaccine production is the belief that vaccines made from viruses grown in these substrates might be oncogenic. If aneuploidy and infinite life-span are removed, the only criterion for exclusion would be tumorigenicity. It would be of value to carry out a systematic program to determine, in general, whether or not there are transmissible oncogenic factors in extracts of homologous tumorigenic cells or in vaccines made from noninfectious viruses propagated in them. (15 refs)

- 79-5455 Distinctive Mechanisms in Naturally Occurring Genetic Resistance to Leukemogenesis. (Eng) Steeves, R. A. (Albert Einstein Coll. Medicine, Bronx, NY); Moore, M. A.; Till, J. E.; Parkman, R.; Bennett, M.; Shearer, G. M.; Meruelo, D.; et al. In: *Natural Resistance Systems Against Foreign Cells, Tumours, and Microbes*. Proceedings of an International Conference held 18-22 October 1976, Jenner, CA. Cudkovic, G.; Landy, M.; Shearer, G. M., eds. (New York: Academic Press): 299 pp.; 197-232; 1978.

Genes that control resistance to Friend leukemia virus (FLV) in mice and studies of T suppressor cells and Hh effects are reviewed. The Fv-1 gene is dominant for resistance, with the n and b alleles conferring resistance to murine leukemia virus of the opposite tropism. This resistance is directed against the helper virus in FLV stocks rather than against the virus directly responsible for spleen focus formation. The Fv-2 gene is recessive for resistance to FLV and presents spleen focus formation after FLV infection. The Fv-2 gene may be demonstrable in uninfected mice and may affect an essential step in embryogenesis. In in vitro cultures of bone marrow from resistant C57BL/6 mice, resistance is demonstrated in terms of leukemic transformation and resistance with respect to propagation of the FLV complex. Mitogen-responsive cells are resistant to FLV, but they are the targets of T suppressor cells. The latter are activated by FLV to suppress the former, and the numbers and/or functions of the suppressors are regulated by M cells. An interfering cell interacts with the H-2D gene product of the mitogen-responsive cells, and H-2D incompatibility between the interfering and mitogen-responsive cells prevents T suppressors from functioning. Susceptibility or resistance in vitro is not linked

REVIEW

with Fv-2. A restricted suppressor cell in AKR leukemia functions via cell contact; the features of this cell are described. The suppressors are Thy-1-positive. Studies are summarized that indicate that certain tumor cells express Hh antigen on their surface. Hybrid resistance to bone marrow transplantation appears to be a manifestation of lymphoma resistance. Gene(s) regulating cell-mediated lymphocytotoxicity responsiveness to AKR tumor cells have been tentatively mapped to the I-J subregion. The targets involved in marrow rejection and graft-vs-host reactions are discussed. (no refs)

- 79-5456 **The Physiopathology of Friend Leukemia.** (Eng) Tambourin, P. E. (Unité de Physiologie Cellulaire INSERM, Unit 22, Institut Curie, Batiment 110, Faculté Paris-Sud, 91405 Orsay, France); Wendling, F.; Jasmin, C.; Smadja-Joffe, F. *Leuk Res* 3(3): 117-129; 1979.

The physiopathology of Friend and Rauscher leukemias (FL and RL), which appear to be multiple-step, virus-induced malignant diseases, is reviewed. The sequence of events in the course of these leukemias is remarkably reproducible. Early events occur as soon as 30 hr after virus infection and result in the massive appearance of hyperbasophilic cells, mainly in the spleen. These cells, which look like proerythroblasts, undergo a pathological erythropoietic differentiation without erythropoietin. They derive from the morphological transformation of erythropoietin-responsive cells or closely related precursors. This initial phase can be characterized as a malignant compartmental disorganization: pathological erythroid cells have a finite life-span, but the size of the compartment of erythroid precursors is uncontrolled, and its inflation leads to the death of leukemic mice. A second step, characterized by the emergence of truly malignant cells, takes place much later. The characteristics of the pre- and neoplastic cell populations that result from these two major steps suggest that they are probably related to each other. In contrast to spontaneous or chemically induced carcinogenesis the multiple-step model is rare in viral oncogenesis. However, it cannot be excluded that this is in fact the case for most virus-induced leukemias. The FL process may provide a unique model for the study of the transforming event itself (leading to the appearance of pathological cells with a definite life span) and the sequence of events involved in the outgrowth of tumor cells. - 79-5457 **Role of Hepatitis B Virus in Primary Liver Cancer.** (Eng) Zuckerman, A. J. (Dept. Medical Microbiology, London Sch. Hygiene and Tropical Medicine, Univ. London, London, England). *J Toxicol Environ Health* 5(2/3): 275-280; 1979.

The role of hepatitis B virus (HBV) in the etiology of primary hepatocellular carcinoma is reviewed. There is an excess prevalence of markers of active infection with HBV in patients with primary liver cancer in many parts of the world. Early age of infection with HBV is likely to be an important factor, resulting in persistent infection that may progress to chronic liver damage. Results of recent experimental studies are consistent with the integration of HBV DNA with host cell DNA molecules. It is likely that primary liver cancer is the cumulative result of several cofactors, including infection with HBV; genetic, immunologic, hormonal, and nutritional factors; and environmental factors, including mycotoxins and chemical carcinogens. (18 refs)

- 79-5458 **Mammary Tumor Viruses.** (Eng) Moore, D. H. (Dept. Microbiology and Immunology, Hahnemann Medical Coll. and Hosp., Philadelphia, PA); Long, C. A.; Vaidya, A. B.; Sheffield, J. B.; Dion, A. S.; Lasfargues, E. Y. *Adv Cancer Res* 29: 347-418; 1979.

An extensive review is presented of mammary tumor viruses (MTV). The topics covered include the morphology of MTV, structural proteins and RNA-directed DNA polymerase of murine MTV (MuMTV), synthesis and assembly of MuMTV proteins, genome of MuMTV, in vivo infection and tumorigenesis of MuMTV, infectivity of endogenous MuMTV, dependence of MuMTV infectivity on mouse strain, transmission of MuMTV by contact, in vitro infection of cells by MuMTV, techniques for and results of antigenic characterization of MuMTV and its components, humoral and cellular immune responses of the host to MuMTV, modulation of the immunologic interaction between MuMTV and its host, and the possibility of an MuMTV-related virus in humans. (279 refs)

- 79-5459 **Introduction--Heterogeneity of the Cellular Immune Response.** (Eng) Dvorak, H. F. (Dept. Pathology, Massachusetts General Hosp., Boston, MA). *Adv Exp Med Biol* 114: 369-374; 1979.

The relevance of nonlymphoid cells in immune reactions is reviewed. When sensitized guinea pigs were injected ip with line 1 or line 10 tumor cells, the principal finding 1-3 days later was variably sized aggregates of inflammatory and damaged or dying tumor cells. Injection of tumor cells into the skin of sensitized animals without BCG led to a reaction involving extensive local infiltrations of basophils (which accounted for 12%-23% of the total inflammatory cells). Frequent intimate associations between infiltrating basophils and viable and necrotic tumor cells were observed. Within hours after injection of line 1 cells into the sc space of unsensitized guinea pigs, the tumor cells formed clumps and became invested in a semirigid, fibrin-gel cocoon. This mass became vascularized by day 3 and was subsequently replaced by fibrous connective tissue. Beginning at about day 8, there was evidence of developing cellular immunity. The tumor cells showed progressive evidence of damage during this period, culminating in widespread tumor death. Tumor cell injury and necrosis were preceded by and correlated with substantial and widespread microvascular compaction and damage to the endothelium of the small vessels supplying the tumor cells and the surrounding connective tissue. The pattern of necrosis had many characteristics of ischemia progressing to infarction, and the microvascular changes observed may have had an immunological basis. The data indicate that the response of the host to the same inoculum of tumor cells varies enormously, depending on the immune status of the host and the site of injection. (19 refs)

- 79-5460 **NK Cell Systems as Effectors of Resistance to Normal and Malignant Hemopoietic Cells.** (Eng) Wigzell, H. (Univ. Uppsala, Uppsala, Sweden); Cudkovicz, G.; Elkins, W. L.; Boranic, M.; Henney, C. S.; Sprent, J.; Festenstein, H.; et al. In: *Natural Resistance Systems Against Foreign Cells, Tumors, and Microbes*. Proceedings of an International Conference held 18-22 October 1976, Jenner, CA. Cudkovicz, G.; Landy, M.; Shearer, G. M., eds. (New York: Academic Press): 299 pp.; 173-196; 1978.

The relationship of natural killer (NK) cells in rats and mice to

marrow and leukemia resistance is reviewed. The initiation of lysis by NK cells is extremely rapid, indicating that there is some kind of induction of a cytolytic capacity via in vitro contact with target cells. The NK cell functions as though its lytic ability were mediated via receptors it produces itself. A considerable variation in target cell sensitivity is evident in various kinds of NK cell systems. There is no indication that the receptors on NK cells are related to conventional immunoglobulins. There is a direct correlation between NK cell activity as measured in vitro and the ability to passively transfer protection against Moloney lymphomas. NK activity is transferred by fetal liver irrespective of the host genotype. There is no indication as to the exact nature of the target structures or what determines sensitivity, although sensitive targets have been found only among hematopoietic cells. Antiserum against Ly1.2 appears to selectively eliminate NK cells from a heterogeneous lymphocyte population. In an irradiated animal, NK cells return within 3 wk after transplantation of bone marrow cells. It is possible that the NK cell is in the granulocytic lineage, perhaps at an early stage of differentiation, although there are arguments against this view. Both NK and T cells could play important roles in surveillance against tumors, perhaps responding to different types of stimuli. A macrophage-type cell can markedly suppress the activity of NK cells in the cytotoxicity assay. The NK cell, resistance to bone marrow transplantation, and resistance to leukemia are intimately related. However, there is no evidence that the same cell is responsible for all three phenomena. (no refs)

- 79-5461 Macrophages and Immunity: Mechanisms and Effects of Macrophage Activation. (Fre) Dumont, A. (Faculte de Medecine, Departement de Pathologie, Universite de Montreal, Montreal, P.Q. H3C 3J7, Canada). *Union Med Can* 108(6): 705-710; 1979.

Recent experimental work defining the nature and role of the macrophage in immune reactions is reviewed. Evidence obtained in in vivo and in vitro studies shows that activated macrophages have cytostatic and/or cytolytic effects on tumor cells. Various substances, including (polyanionic compounds, endotoxins, and lipopolysaccharides, can activate macrophages. The substances released by macrophages that cause cytostasis or cytolysis are thought to be hydrolytic enzymes. The role of complement and lymphokines in the cytostatic and cytolytic activity of macrophages is discussed. At this time, none of the animal studies of macrophage antitumor activities have been verified in humans. (14 refs)

- 79-5462 Thymic Functions and Resistance to Foreign Hemopoietic Grafts. (Eng) Stutman, O. (Memorial Sloan-Kettering Cancer Center, New York, NY); Warner, N. L.; Elkins, W. L.; Cudkowicz, G.; Sprent, J.; Golub, E. S.; Bennett, M.; et al. In: *Natural Resistance Systems Against Foreign Cells, Tumors, and Microbes*. Proceedings of an International Conference held 18-22 October 1976, Jenner, CA. Cudkowicz, G.; Landy, M.; Shearer, G. M., eds. (New York: Academic Press): 299 pp.; 31-45; 1978.

The restoration, by grafting, of T-cell function in athymic recipients is reviewed. In contrast to syngeneic thymus grafts, allogeneic grafts produce poor immunological restoration of neonatally thymectomized mice, and the allogeneic grafts are not repopulated and only rarely acquire the appearance of a normal thymus. In unirradiated recipients, there appears to be strict histocompatibility restrictions between the thymus and migrating

hematopoietic cells. When an F₁ thymus is grafted into parental strains, tolerance induction to skin of the same origin is dependent on the strain combination used. Graft-vs-host (GVH) reactivity is a restricted event. There is no evidence of Hh gene expression on thymus cells. Data support the idea that genetic resistance is exerted upon T- and B-lymphocyte clones. In the thymus there are two sets of cells: cortisone-sensitive and nonfunctional and one cortisone-resistant and functional in the periphery. The role of the cortisone-resistant cells within the thymus is unknown. T cells are not involved in anti-Hh responses in vivo, marrow graft rejection being stronger in the absence of these cells. However, in vitro, where the end point is lysis rather than cytoablation, the effectors of the F₁ and antiparent responses are Thy-1 positive cells. (no refs)

- 79-5463 Natural Resistance to Foreign Hemopoietic and Leukemia Grafts. (Eng) Cudkowicz, G. (State Univ. New York at Buffalo, Buffalo, NY); Sanford, B. H.; Van Bekkum, D. W.; Bach, F. H.; Storb, R.; Warner, N. L.; Moore, M. A.; et al. In: *Natural Resistance Systems Against Foreign Cells, Tumors, and Microbes*. Proceedings of an International Conference held 18-22 October 1976, Jenner, CA. Cudkowicz, G.; Landy, M.; Shearer, G. M., eds. (New York: Academic Press): 299 pp.; 1-30; 1978.

The features that distinguish bone marrow transplants from other types of grafts are reviewed. By integrating data obtained in vitro and in vivo, a comprehensive model for natural resistance to normal and malignant hematopoietic grafts was derived. Central to all manifestations of such anti-Hh (anti-hematopoietic histocompatibility) reactions is a macrophagelike cell that interacts in vivo with the effectors (or their precursors) of resistance. These in vivo effectors are conspicuous with respect to their lack of T-cell markers and their low sensitivity to radiation. They are viewed as subpopulations differing essentially in the target cell structure they recognize, ie, in their specificity. In vitro, the same central macrophagelike cell interacts with T cells in the generation of F₁ antiparent cytotoxicity. The genetic control operates at two levels. The H-2 region may be involved in determining the nature or expression of the Hh antigens, and it also may be involved in controlling the immune response to various cell-surface antigens. The data presented and a proposed model are discussed by a panel. (no refs)

- 79-5464 Observations on Immunology and Oncology of Paraproteins. (Ger) Mey, U. (Med. klinik der Med. Akademie, Leipziger Strasse 44, DDR-20 Magdeburg, E. Germany). *Z Gesamte Inn Med* 34(7): 182-185; 1979.

Paraproteins (M proteins: M-PT's) were long considered abnormal proteins not found in normal human plasma. Recently, amino acid analyses have shown that M-PT's have the same structure as some immunoglobulins; in some diseases, a cell clone produces abnormally large amounts of M-PT. Fragments of M-PT, designated heavy and light chains, are also found in these diseases. M-PT's are found not only in classic monoclonal gammopathies, but also in Hodgkin's disease and autoimmune diseases (ulcerative colitis, Crohn's disease). A hypothesis based on results in mice suggests that all lymphomas, including those of humans, result from the activation of a resting oncogenic virus and, thus, a disturbance in the lymphatic cell system. The M-PT would then be a product of tumor virus information incorporated into the genomes of B lymphocytes. The functional characteristics of M-PT's (lymphocytotoxicity, aggregation, binding to blood cells) lead to the

REVIEW

clinical symptoms of M-PT diseases (immune defects, nephropathy, amyloidosis, hemorrhagic diathesis). If these changes in protein structure are caused by an oncogenic virus, benign paraproteinemia would not exist; however, some of the diseases could be classified as having a relatively benign course. - 79-5465 α -Fetoprotein in Cancer and Fetal Development. (Eng) Ruoslahti, E. (Div. Immunology, City Hope Natl. Medical Center, Duarte, CA); Seppala, M. *Adv Cancer Res* 29: 275-346; 1979.

Data on the occurrence of α -fetoprotein (AFP) in cancer and fetal development are reviewed. The topics included are antibodies to AFP, interspecies cross-reactions, immunological cross-reactions between AFP and albumin, immunoassays of AFP in biological fluids, international standard for AFP, detection of AFP synthesis by internal labeling, detection of AFP in tissues, sites of physiological AFP synthesis, physiological concentrations of AFP in body fluids, biological half-life of AFP, purification of AFP, physical and chemical properties of AFP, possible immunoregulatory role for AFP, AFP in liver injury and hepatocarcinogenesis, AFP in germ cell tumors, and the use of AFP levels in the diagnosis of liver diseases, trophoblastic disease, and fetal pathology. (318 refs)

- 79-5466 Biochemical Strategy of Hepatomas. (Eng) Weber, G. (Lab. Experimental Oncology, Indiana Univ. Sch. Medicine, Indianapolis, IN); Kizaki, H.; Shiotani, T.; Tzeng, D.; Williams, J. C. *J Toxicol Environ Health* 5(2/3): 371-386; 1979.

The enzymology and metabolism of hepatomas is discussed in terms of the pattern that reveals the biochemical strategy of the cancer cells. Particular emphasis is placed on aspects of pyrimidine biosynthesis. Included in the discussion are the molecular correlation concept; transformation-linked alterations and progressions in biochemical strategy; evidence for reprogramming of gene expression, such as alterations in enzyme concentration and isozyme pattern; the 'key enzyme' concept; and biological model systems. The linking of enzymatic and biochemical markers with malignant transformation and progression includes reciprocal regulation, a pattern of metabolic imbalance in purine metabolism, imbalance in pyrimidine and DNA metabolism, and enzymatic imbalance in cytidine 5'-triphosphate biosynthesis in hepatomas. The applicability of biochemical imbalance discovered in rat hepatomas to other types of tumors in rodents and in humans, and the biochemical strategy of human hepatomas are considered. It is demonstrated that the biochemical strategy first identified in a series of transplantable rat hepatomas is applicable to human primary hepatomas. (35 refs)

- 79-5467 Antigenic Changes Associated with Liver Carcinogenesis. (Eng) Embleton, M. J. (Cancer Res. Campaign Labs., Univ. Nottingham, University Park, Nottingham, England). *J Toxicol Environ Health* 5(2/3): 453-468; 1979.

Cells undergoing neoplastic transformation after treatment with chemical carcinogens often express antigens that are not expressed in their normal counterparts in adult hosts. These individually

distinct antigens are capable of inducing tumor immunity in syngeneic hosts. They arise as a consequence of cell-carcinogen interaction, and they may result from the modification or replacement of normal cell-surface components. Their role in immunosurveillance is not established, but they offer a target for tumor immunotherapy. Reexpressed fetal antigens have also been detected, either as secretory products (α_1 -fetoprotein) or as common cell-surface components, on hepatoma cells. These antigens may be important diagnostic indicators of neoplastic change. Common antigens initiated early after carcinogen treatment, before malignant cells are detected, are possibly associated with the fetal antigens. Together, the antigens associated with liver carcinogenesis may prove to be powerful tools in understanding the process of liver neoplasia. (68 refs)

- 79-5468 Anorexia Pancreatica. (Rus) Vasilenko, B. Kh. (No affiliation given). *Klin Med (Mosk)* 57(6): 19-21; 1979.

Difficulties encountered in the early diagnosis of pancreatic cancer are reviewed briefly. The initial complaints include epigastric or back pain (approx 50% of the patients) and jaundice (25%-30%). The most important symptom was found to be a complete loss of appetite (anorexia pancreatica). It was suggested that the anorexia is caused by a severe inhibition of the alimentary canal. (no refs)

- 79-5469 Use of Nude Mice for Studies on the Tumorigenicity of Animal Cells. (Eng) Freedman, V. H. (Dept. Genetics, Albert Einstein Coll. Medicine, Yeshiva Univ., Bronx, NY); Shin, S. In: *The Nude Mouse in Experimental and Clinical Research*. Fogh, J.; Giovanella, B. C., eds. (New York: Academic Press): 502 pp.; 353-384; 1978.

The use of the nude mouse as a means of determining the tumorigenicity and tumor growth patterns of animal cells is reviewed. In most cases, the nude mouse is immunologically oblivious to the injected cells, so that the formation of tumors can be attributed solely to intrinsic cell properties. Established cell lines and virally transformed cells able to proliferate without anchorage in vitro are capable of generating tumors in nude mice. When nontumorigenic cells are passaged in semisolid medium, clones showing anchorage independence also show an ability to form tumors in nude mice. Passage of poorly tumorigenic cells through methylcellulose leads to an enrichment of anchorage-independent cells with greatly enhanced tumorigenicity. Thus, there appears to be an intimate and specific relationship between the anchorage-independent phenotype in vitro and the ability of a cell to generate tumors in the nude mouse. Several structural and functional parameters have been associated with tumorigenic potential in the nude mouse; eg, actin cables in the cytoplasm and the synthesis and secretion of plasminogen activator. In general, host cell transformation and recruitment are not involved in tumor growth, and the absence of induction of host-specific endogenous viruses or tumor cell-specific latent viruses during tumor growth was demonstrated in at least one instance. Cell-specific biochemical, chromosomal, and antigenic markers are not demonstrably altered during tumor growth, and there is extensive evidence that tumors that develop in nude mice after implantation of heterologous malignant tumor retain the original tumor histopathology. (36 refs)

- 79-5470 The Growth Behavior of Virus-transformed Cells in Nude Mice. (Eng) Stiles, C. D. (Dept. Microbiology and Molecular Genetics, Harvard Medical Sch., Boston, MA); Kawahara, A. A. In: *The Nude Mouse in Experimental and Clinical Research*. Fogh, J.; Giovanella, B. C., eds. (New York: Academic Press): 502 pp.; 385-409; 1978.

The tumorigenic behavior of cell cultures derived from normal and neoplastic tissues in nude mice is reviewed, as is the available data on the tumorigenic behavior of viral-transformed cells in nude mice. Tumorigenicity of animal and human cell cultures in athymic nude mice is generally a reliable indicator of neoplastic potential. Under conditions in which most cell lines derived from human tumors are tumorigenic in nude mice, most human fibroblast and lymphocyte cultures transformed by DNA viruses are not tumorigenic. However, cell cultures that fail to form tumors in nude mice cannot automatically be described as "normal". The integration of DNA virus genetic material is insufficient for malignant behavior in vivo. There is some evidence that the integration of RNA tumor virus genomes is sufficient for neoplastic behavior, but the data are too scanty for generalizations to be made. Of the in vitro criteria that define the transformed state, there is no single parameter that is a sufficient indicator of tumorigenic potential in nude mice. Studies of the tumorigenicity of virus-transformed cells in nude mice may shed light on the physiological nature of growth-regulatory signals and clarify the extent to which individual virus species constitute an oncogenic threat to humans. (42 refs)

- 79-5471 Spontaneous, Viral, and Chemically Induced Tumors in the Nude Mouse. (Eng) Stutman, O. (Memorial Sloan-Kettering Cancer Center, New York, NY). In: *The Nude Mouse in Experimental and Clinical Research*. Fogh, J.; Giovanella, B. C., eds. (New York: Academic Press): 502 pp.; 411-435; 1978.

The growth of spontaneous and of virally and chemically induced tumors in the nude mouse is reviewed. Previous investigators have reported an absence of tumors in nude mice or, conversely, an inordinately high incidence of lymphomas in these animals. However, controlled experiments indicate that the incidence and types of spontaneous tumors in nude mice are basically comparable to those in immunologically normal control mice. Both the tumor incidence and type in nude mice follow those in the inbred strain from which the nude animals are derived. There is more general agreement on the oncogenic effects of DNA and RNA oncogenic viruses in nude mice. Nude mice partially inbred to various background strains showed increased susceptibilities to tumor induction with polyoma viruses. Similar studies showed that nude mice can, under certain circumstances, develop alternative immune responses that can act as surveillance devices. Both nude and normal control mice developed a 100% incidence of tumors following infection with Moloney sarcoma virus, but regressions were observed only in the normal animals. Thus, the thymus dependence of tumor regression is unquestionable. The focus-forming component of Friend leukemia virus can be detected in nude mice infected with this virus. The actual tumor incidence and latency periods for tumor development in nude mice and their immunologically normal controls are generally comparable following treatment with chemical carcinogens. In general, the data indicate that there is no clear correlation between the immune deficiency of nude mice and any form of peculiar risk for tumor development. (47 refs)

- 79-5472 Transplantation of Heterologous Endocrine Tumor Cells in Nude Mice. (Eng) Reid, L. C. (Dept. Biology,

Muir Coll., Univ. California at San Diego, La Jolla, CA); Shin, S. In: *The Nude Mouse in Experimental and Clinical Research*. Fogh, J.; Giovanella, B. C., eds. (New York: Academic Press): 502 pp.; 313-351; 1978.

The transplantation of heterologous endocrine tumor cells in nude mice is reviewed. Many transplantable lines derived from hormone-secreting and -dependent tumors have been established in nude mice. All tissues, whether normal, benign, or malignant, may survive indefinitely when implanted in nude mice, although benign tumors eventually cease growing. There is a variably long "adaptation period" for the transplanted tumor in the first passages; the ability to vascularize appears to be one of the important factors in this variability. The tumor lines established in nude mice usually retain their morphological and biochemical differentiation through serial transplantation. However, the tumors show a gradual enrichment for the fastest growing tumorigenic cells with a gradual elimination of the normal and benign components in the original specimen. Not all heterologous specimens will produce tumors in nude mice, and the site of implantation may be an important factor for growth. The development of transplantable endocrine tumor lines from functional tumors may be prevented if the tumors secrete lethal amounts of a hormone, unless the transplant recipient can be "preconditioned" by surgery, etc, so that the lethal effect can be circumvented. The transplantable tumor lines maintained in nude mice are expected to provide model systems for studies of hormone synthesis and secretion, determination of hormone requirements for the growth of specific endocrine cells, and for the purification of new hormones. (36 refs)

- 79-5473 Cellular Differentiation, a Problem in Oncology. (Por) Silvany, A. M. (Departamento Histologia e Embriologia, Fac. Med. Univ. Federal da Bahia, Bahia, Brazil). *Rev Bras Cancerol* 28(4): 61-73; 1978.

Data on the process of differentiation are reviewed, particularly studies at the molecular level. Differentiation is due to selective gene-regulation mechanisms, and cancer could result from aberrant gene regulation. Metaplasia and the histologic grading of malignant tumors are also reviewed. (35 refs)

- 79-5474 The Role of Inheritance in Malignant Disease. (Ger) Muller, H. (Abteilung Genetik, Universitäts-Kinderklinik, Romergasse 8, CH-4005 Basel, Switzerland). *ZFA (Stuttgart)* 55: 917-923; 1979.

Studies of genetic factors involved in cancer development show that individual differences in response to carcinogens (viruses, chemicals, and ionizing radiation) are due to the genetic factors. On the other hand, the cancer risk of familially predisposed subjects is also influenced by environmental factors. (10 refs)

- 79-5475 Development of a Neonatal and Metastatic Murine Neuroblastoma Model (2 Letters to Editor). (Eng) Lueker, D. C. (Dept. Microbiology, Colorado State Univ., Fort Collins, CO 80523); Stewart, I. B.; Kainer, R. A.; Schengrund, C. L.; Repman, M. A.; Sheffler, B. A. *Cancer Res* 39(8): 3277-3278; 1979.

Conflicting findings obtained in two studies of a neonatal and metastatic murine neuroblastoma model are discussed. In the first

study, mice inoculated sc with 5×10^5 cells did not develop metastasis, but metastasis did occur when 2×10^5 cells were injected id. In the second study, metastases were observed when the mice were inoculated sc. Also, in contrast with the first study, reduced mortality was observed when the same number of tumor cells were injected id. However, the contrasting results could be due to a difference in the neuroblastoma lines used: a cloned line was used in the first study and an uncloned C-1300 neuroblastoma was used in the second. Cloning may select for certain characteristics that may or may not alter the in vivo behavior of the cells. (6 refs)

- 79-5476 Role of Genetic Disorders in Retinoblastoma. (Pol) Sporny, S. (Zaklad Anatomii Patologicznej, Instytut Patologii AM, ul. Narutowicza 96, 90-139 Lodz, Poland); Pruszczyński, M. *Pol Tyg Lek* 34(3): 107-109; 1979.

Studies of retinoblastoma and its relationship to genetic disorders are reviewed. Retinoblastoma has been found to be associated with trisomy 21, tetrasomy (48, XXX, G+ or 48, XXY, G+), or ring chromosome 13 (46, XX, Dr or 46, XY, Dr). (24 refs)

- 79-5477 Tumors of the Eyeball. (Ger) Fanta, H. (Augenabteilung der Krankenanstalt Rudolfstiftung, Ferstelgasse 4, A-1090 Vienna, Austria). *Klin Monatsbl Augenheilkd* 174(3): 411-420; 1979.

After a classification of tumors of the eyeball as benign vs malignant or pigmented vs nonpigmented, attention is drawn to the fact that most of these tumors lie in the palpebral fissure and are benign. Leukoplakia is a clinical description but not a diagnosis. Leukoplakia can be used to describe both benign and malignant growths. Intraepithelial epithelioma is often incorrectly diagnosed as Bowen's disease. This disease of the skin and intraepithelial epithelioma of the limbus are histologically quite different, and, therefore, the term Bowen's disease is incorrect. Not all the various tumors occur with the same incidence; eg, squamous cell carcinoma occurs more often in some countries than in others. Malignant melanomas of the conjunctiva are not as malignant as those of the caruncle or cornea. In the conjunctiva, secondary melanomas can occur after penetration of an intraocular melanoma through the sclera; similarly, metastases can occur in the form of epibulbar tumors. In all cases, the epibulbar tumor should be excised carefully. A histological examination is necessary for diagnosis. (19 refs)

- 79-5478 Neck Mass of Uncertain Etiology. (Eng) Clairmont, A. A. (Dept. Surgery, Emory Univ. Sch. Medicine, Atlanta, GA); Richardson, G. S. *Pennsylvania Med* 82(8): 29-31; 1979.

A systematic diagnostic approach to the patient with a neck mass of uncertain etiology is reviewed. Ninety percent of all isolated neck masses in adults are metastatic carcinomas, and 90% of these are metastatic from primaries above the clavicle. However, involved supraclavicular nodes usually have a primary site below the clavicle. Approx 40% of the primary head and neck lesions in adults involve the laryngopharynx, 40% involve the oropharynx, and 10% involve the thyroid. In children, carcinoma accounts for only approx 33%-60% of malignant disease. In children, masses

occurring in the posterior triangle, unilateral node enlargement, or the presence of a node larger than adjacent lymphoid structures are causes for concern. In the adult, the location suggests a different approach to diagnosis of the etiology. The search for the primary lesion may involve laboratory studies, roentgenologic studies, panendoscopy, and needle aspiration biopsy of the mass. The excisional biopsy should be followed by definitive surgery and, possibly, radical neck dissection. The need for close follow-up examinations of all patients with occult primary lesions is stressed. (13 refs)

- 79-5479 Anatomical Features of the Origin and Spread of Tumours. (Eng) Levene, A. L. (Dept. Histopathology, Royal Marsden Hosp., London, England). *Ann R Coll Surg Engl* 60(1): 28-35; 1978.

The part played by anatomical factors in determining variations in the origin, distribution, shape, and mode of spread of different tumors is discussed, and the need for surgeons to bear these factors in mind in diagnosis and treatment is emphasized. Tables listing sites of predilection for bone tumors, the anatomical distribution of some nonepithelial neoplasms, and sarcomas that metastasize to lymph nodes in a significant proportion of cases are presented. (10 refs)

- 79-5480 Birthmarks: II. Melanocytic and Epidermal Nevi. (Eng) Jacobs, A. H. (Dept. Dermatology, Stanford Univ. Sch. Medicine, Stanford, CA). *Pediatrics* 1(2): PIR47-PIR50; 1979.

Data on melanocytic and epidermal nevi are reviewed. The acquired melanocytic nevi usually develop between the second and sixth year and may appear in crops at puberty. The individual risk of eventual malignant transformation is only about 1/1,000,000. The location and histologic type of the nevus are not related to the likelihood of such transformation. A truly congenital nevus should have its history dating to the actual time of birth. The incidence of malignant melanoma arising in these nevi may approach 10%, and 60% of the melanomas that have occurred in congenital nevi have done so during the first decade of life. Cafe-au-lait spots are usually present at birth or they appear in early childhood. When six or more spots are present, especially if they are ≥ 1.5 cm in diameter, there is a strong possibility that the patient has, or will develop, neurofibromatosis. Cafe-au-lait spots are also associated with tuberous sclerosis, pulmonary stenosis, and temporal lobe dysrhythmias. The most common epidermal nevi are the verrucous nevus and sebaceous nevus. Both are either congenital or appear within the first year. Total surgical excision is the treatment of choice for sebaceous nevi, since basal cell carcinoma may eventually develop during middle life. The epidermal nevus syndrome is one in which an extensive epidermal and/or sebaceous nevus is associated with multiple skeletal and neurologic abnormalities. (8 refs)

- 79-5481 Amyloid Disease. General Review. (Fre) Vincent, J. P. (Hopital Louis Mourier, F 92701 Colombes Cedex, France); Hardouin, J. P.; Devars Du Mayne, J. F. *Rev Fr Gastroenterol* (149): 47-50, 53; 1979.

The histological diagnosis of amyloid disease based on identification of the infiltration of organs with amyloid substance (AS) is reviewed. The different types of amyloid disease include primary

hereditary amyloid disease of endocrine tumors or APUD (amine precursor uptake and decarboxylation) amyloidosis, senile amyloid disease, and amyloid disease secondary to other diseases, such as cancer. Amyloidosis can be a complication of Hodgkin's disease, chronic lymphoid leukemia, and, less frequently, cancer of the viscera. Tumors of the APUD system secrete a substance that takes up histological stains in a manner similar to that of AS but differs from AS biochemically. The relationship between AS and immunoglobulins is discussed. Animal experiments show that prolonged immunological stimulation can result in amyloid disease. In the induction phase of amyloid disease in animals, there is an increase in plasma α_2 -globulins and γ -globulins and a proliferation of reticuloendothelial cells. (9 refs)

- 79-5482 Kupffer Cell Suspensions and Cultures as a Tool in Experimental Carcinogenesis.** (Eng) Munthe-Kaas, A. C. (Dept. Pathology, Norsk Hydro's Inst. Cancer Res., Norwegian Radium Hosp., Montebello, Oslo, Norway). *J Toxicol Environ Health* 5(2/3): 565-573; 1979.

The interactions of Kupffer cells, phagocytes lining the sinusoids, and hepatocarcinogens are reviewed. Environmental carcinogens must first traverse a Kupffer cell barrier before reaching the liver parenchyma. Phagocytosis and subsequent degradation of carcinogens by Kupffer cells lead to their permanent removal. Factors such as membrane receptors, which determine the avidity of Kupffer cells for various substances, would consequently have a decisive role in the primary interaction between carcinogens and Kupffer cells. Likewise, the intracellular lysosomal apparatus, which determines the ability of these cells to degrade various substances, would determine whether these substances can persist in an active form. In vivo data on Kupffer cell clearance of various substances are plentiful. However, to dissect the complex problem of Kupffer cell interaction with carcinogens, a clear-cut in vitro system would be useful. A system for separating Kupffer cells from other types of liver cells and maintaining pure Kupffer cell cultures has been achieved in recent years. Some basic cell biology studies, such as studies of membrane receptors and lysosomal enzyme apparatus, have already been made. (57 refs)

- 79-5483 Gut Endocrine Tumour Syndromes.** (Eng) Holst, J. J. (Inst. Medical Physiology C, Univ. Copenhagen, Copenhagen, Denmark). *Clin Endocrinol Metab* 8(2): 413-432; 1979.

Gastrointestinal tract endocrine tumor syndromes except for carcinoid tumors and the Zollinger-Ellison syndrome, are reviewed with emphasis on advances of clinical relevance. In recent years, a number of new cells have been characterized, and peptides that were originally found in nervous tissue have been localized to endocrine cells in the gastroenteropancreatic system. Nothing is known about the etiology of the gastrointestinal tract endocrine tumors, although inheritance may play a role in some instances. A ductular origin is suspected for most of the pancreatic tumors. The following main syndromes are discussed: the Verner-Morrison syndrome; the insulinomas; the glucagonoma syndrome; stomatostatinoma; and multiple endocrine adenopathy. The diagnosis of a gut endocrine tumor often rests on the demonstration of hypersecretion of the gastrointestinal peptides. Since these measurements do not necessarily reveal the site of hypersecretion, however, localization procedures such as selective angiography, ultrasound and computed tomography, and selective venous sampling are important. (89 refs)

- 79-5484 Carcinoma of the Gastric Stump.** (Ger) Luders, K. (Chirurgische Klinik, Nordwestkrankenhaus, Steinbacher Hohl 2-26, D-6000 Frankfurt/Main 90, W. Germany); Radomsky, J.; Ungeheuer, E. *Med Klin* 74(14): 91-100; 1979.

The epidemiology and diagnosis of carcinoma of the gastric stump (GSC) are reviewed. This lesion is defined as a carcinoma found in the gastric remnant at least 5 yr after surgical removal of part of the stomach because of benign disease. The age distribution and histology of GSC are similar to those of primary gastric carcinoma (PGC). Many studies have established a two- to fourfold increased risk of carcinoma in subjects who have undergone gastric resection compared with that in the general population. The risk of GSC seems to be greater for patients whose surgery was for peptic ulcers than for those whose surgery was for duodenal ulcers. Epithelial irritation from jejunal reflux and chronic atrophic gastritis with anacidity are suggested causes of the increased risk. The av interval between surgery and GSC is 20-25 yr; the intervals tend to be longer in younger patients ($p < 0.001$). The av time between first symptoms and correct diagnosis was 10 mo for 14 patients with GSC, vs 4.6 mo for those with PGC. Symptoms (wt loss, pressure or pain in the stomach, belching, vomiting) are usually not noted until the GSC is advanced. Endoscopy should be done yearly on patients with gastric remnants up to age 60, and then twice a year, even if they are symptom-free. In GSC patients, the surgical mortality is higher and the survival time is lower than those in PGC patients. (43 refs)

- 79-5485 The Association Between Diabetes Mellitus and Endometrial Carcinoma.** (Ger) Dillinger, P. (Klinikum rechts der Isar, Technische Universität München, Munich, W. Germany); Koeppe, H. W. *Med Klin* 74(8): 284-287; 1979.

A positive association between diabetes mellitus and endometrial carcinoma has been observed in several studies. The hypersecretion of growth hormone or of follicle-stimulating hormone and ACTH by the hypophysis has been suggested to be a cause of both diseases. (47 refs)

- 79-5486 Epithelial Injury by Cystoscopy Fluids.** (Eng) Weinstein, R. S. (Dept. Pathology, Rush-Presbyterian-St. Luke's Medical Center, 1753 W. Congress Parkway, Chicago, IL 60612); Koo, C.; Pauli, B. U.; Jacobs, J. B.; Friedell, G. H. *Semin Oncol* 6(2): 257-259; 1979.

The possibility that cystoscopy fluids may enhance the spread of bladder cancer cells was suggested by observations in laboratory animals. Cancer cells introduced into mouse bladders in which the epithelium had been altered by chemical or thermal trauma were capable of implanting and growing. In addition, exposure of bladder mucosa of normal and tumor-bearing rats to cystoscopy infusion fluids caused epithelial necrosis. Epithelial proliferation occurred as a response to the injury. (4 refs)

- 79-5487 Unilateral Abdominal Cryptorchidism.** (Eng) Hinman, F. (M-553, Univ. California, San Francisco, CA 94143). *J Urol* 122(1): 71-75; 1979.

The unilateral nonpalpable undescended testis, one entity of the cryptorchidism complex, is more prone to malignancy. The risk of

malignancy is 35 times greater for persons with cryptorchidism than for the general population. Intraabdominal testes have an even higher risk of malignancy. Although no more than 15% of undescended testes are intraabdominal, they contain half of the tumors. Testicular dysgenesis rather than exposure to increased temperature appears to be the major factor leading to neoplasia, as the testis is subjected to the same elevated temperature whether it is within the abdominal cavity or lying in the groin. It has been asserted that early orchiopexy reduces the likelihood of malignancy, but no convincing evidence has been presented. The risk of eventual death from carcinoma in a prepubertal boy with an abdominal testis is almost 6%, much higher than the 0.2% chance of a fatal outcome from orchiectomy. The risk of malignancy is concluded to be great in an abdominal testis, whether up or down, and probably warrants its removal when there is a contralateral testis. (73 refs)

- 79-5488 Gastric Stump Carcinoma--Carcinogenic Factors and Possible Preventive Measures. (Eng) Schonleben, K. (Abt. Allgemeinchirurgie, Chirurgische Universitätsklinik, Jungeblutplatz 1, 4400 Munster, W. Germany); Langhans, P.; Schlake, W.; Kautz, G.; Bunte, H. *Acta Hepatogastroenterol (Stuttg)* 26(3): 239-247; 1979.

Clinical experience with gastric stump carcinoma is reviewed. The type of procedure used in the primary resection and the local irritation accompanying execution of the anastomosis may be involved in the etiology of the malignant transformation. The use of resorbable sutures and a surgical procedure that avoids reflux is recommended. Periodic postoperative radiologic, endoscopic, and histologic studies are essential. (46 refs)

- 79-5489 Ultrastructure of Hepatocellular Tumors. (Eng) Hruban, Z. (Dept. Pathology, Univ. Chicago, Chicago, IL). *J Toxicol Environ Health* 5(2/3): 403-431; 1979.

The lesions that appear during hepatocarcinogenesis in the rat can be separated into morphologically different entities which, when arranged in sequence, are thought to be the morphological stages in the carcinogenic process. The primary and transplantable hepatocellular carcinomas can also be arranged in a sequence thought to represent the progression toward the ultimate cancer cell. Studies of rat, murine and human hepatocarcinogenesis are reviewed. Hepatocellular tumors have been induced in the rat by nitrosomorpholine, diethylnitrosamine, N-2-fluorenylacetylamide, azo compounds and other carcinogens. Lesions derived from hepatocytes can be differentiated from those originating in other cellular components of the liver. In the early stages of carcinogenesis, there is variability and divergence in the structure of cellular organelles; the cellular structure and organelles become more simplified with progression of the cancer, and no qualitative changes specific for cancer cells exist. Toxic changes associated with the carcinogenic process are listed. As hepatocellular cancer progresses, decreases are observed in the number and complexity of microbodies, reductions are seen in the mitochondrial cristae and the tubulovesicular form of smooth reticulum, accumulation of free ribosomes occurs, increases are observed in the granular component, and condensation of the fibrillar component is seen. The neoplastic tissue exhibits an increased mitotic rate. (132 refs)

- 79-5490 Pathology of Primary Liver Cancer. (Eng) Lapis, K. (First Dept. Pathology, Semmelweis Medical Univ.,

Budapest, Hungary); Johannessen, J. V. *J Toxicol Environ Health* 5(2/3): 315-355; 1979.

Current knowledge of the etiology and pathogenesis of primary hepatocellular carcinoma (PHC) in humans is briefly reviewed; and the gross, histopathologic, and ultrastructural features of the variants of this tumor are emphasized. The geographic variations in PHC frequency are attributable in part to the occurrence of carcinogens such as aflatoxin B1, other aflatoxins, cycasin and pyrrolizidine alkaloids. The association of PHC and liver cirrhosis is discussed, as is the oncogenic effect of hepatitis B virus. The relationships between hormone treatment and the development of liver cell carcinoma and between continuous use of oral contraceptives and liver cell adenomas are mentioned. The pathology of PHC is discussed with regard to the gross appearance, light microscopic findings, and electron microscopic appearance. Difficulties in differential diagnosis occur mainly when the tumors are of the combined or mixed type, contain formations that resemble bile ducts, or when they are undifferentiated or of the clear cell variety. The mode of spread of PHC is reviewed. The prognosis of PHC is very poor due to the late diagnosis. (181 refs)

- 79-5491 Precancerous Changes in the Human Liver. (Eng) Anthony, P. P. (Dept. Pathology, Univ. Exeter, Exeter, Devon, England). *J Toxicol Environ Health* 5(2/3): 301-313; 1979.

There is comparatively little knowledge of the cellular events that precede neoplasia in the human liver. Cirrhosis is a common antecedent or accompaniment of liver cell carcinoma, and it seems that both its etiology and its duration are relevant risk factors. Many cellular changes have been observed in patients and among populations considered to be at risk. Of these, liver cell dysplasia is the most striking, and studies of its prevalence, natural history, and association with particular forms of cirrhosis suggest that it is a precancerous change. Bile duct carcinoma may follow infestation with liver flukes and ductal epithelial hyperplasia is present before the development of cancer. Angiosarcoma from several causes is commonly preceded by portal and capsular fibrosis, vascular changes, and Kupffer cell hyperplasia. (50 refs)

- 79-5492 Hepatocyte Suspensions and Cultures as Tools in Experimental Carcinogenesis. (Eng) Seglen, P. O. (Dept. Tissue Culture, Norsk Hydro's Inst. Cancer Res., Norwegian Radium Hosp., Montebello, Oslo, Norway). *J Toxicol Environ Health* 5(2/3): 551-560; 1979.

Techniques for the isolation of preneoplastic cell populations and their application in the analysis of the development of liver cancer are discussed. The preparation and purification of isolated rat hepatocytes can be accomplished in the following steps: 1) a two-step collagenase perfusion of the isolated rat liver using Ca^{2+} free buffer in the first 10 min and collagenase with Ca^{2+} for 10 min; 2) mechanical disruption of the collagenase-perfused tissue with a stainless steel comb; 3) filtration through a nylon mesh; 4) purification of hepatocytes by differential centrifugation. Thus far, transformed cells have not been separated from normal hepatocytes in the cell suspensions obtained after collagenase dispersion of the liver. The application of hepatocyte cultures to the screening of chemical carcinogens is discussed as a possible supplement to the bacterial test systems currently in use. Although proliferating cultures of true hepatocytes have not been established, these cells would make an ideal system for the testing of cell

transformation by chemical carcinogens. Further work is needed. (75 refs)

- 79-5493 The Pattern of Disease in the Post-infection Era: National Trends. (Eng) Doll, R. (Dept. Regius Professor Medicine, Radcliffe Infirmary, Woodstock Road, Oxford OX2 6HE, England). *Proc R Soc Lond [Biol]* 205(1158): 47-61; 1979.

Trends in mortality among British infants, children, and persons aged 45-64 yr during 1931-1975 are reviewed. Among infants, all causes of death except congenital anomalies have decreased, and mortality among children aged 1-14 yr has decreased by nearly 90%. The remaining mortality among children is largely due to violence (32%), neoplasms (17%), and congenital anomalies (15%). Trends in mortality from the principal types of childhood cancer have shown downward trends for several types, including leukemia, Hodgkin's disease, and Wilms' tumor. Among individuals aged 45-64 yr, mortality since 1931 has decreased by 23% in men and by 42% in women. Lung cancer (34% of deaths in this age group) and ischemic heart disease (31%) are among several causes of death that have become more common in this age group, although the rates have declined since 1975. Mortality from cancer of the stomach declined significantly among both men ($p < 0.01$) and women ($p < 0.05$) between 1970 and 1975, whereas non-Hodgkin's lymphoma among men ($p < 0.05$) and cancers of unspecified site among women ($p < 0.05$) have become more common. In total, cancers of 25 sites have varied $<1\%/yr$ since 1931, cancers of 16 sites have decreased progressively by $>1\%/yr$, and cancers of 13 sites have increased by $>1\%/yr$. (9 refs)

- 79-5494 Endocrine Effects of Oral Contraception. (Eng) MacLeod, S. C. (70 Exhibition St., Kentville, Nova Scotia, Canada B4N 1K5). *Int J Gynaecol Obstet* 16(6): 518-524; 1979.

The benefits and risks of oral contraceptive use are discussed, particularly with regard to post-pill amenorrhea. Since 1972, the overall incidence of pituitary adenomas in patients with post-pill amenorrhea or with spontaneous secondary amenorrhea increased from 0% to 26%. However, there is presently no good evidence to suggest that pituitary tumors are more frequent when the amenorrhea is associated with oral contraceptive use. (37 refs)

- 79-5495 Smoking Patterns by Occupation, Industry, Sex and Race (2 Letters to the Editor). (Eng) Bader, M. (No affiliation given); Sterling, T. D. *Arch Environ Health* 34(3): 189; 1979.

Criticism is made of the observation in blacks that a lower smoking rate (vs that for whites) coupled with an increased lung cancer rate is important additional evidence that occupation, and not smoking, bears the major responsibility for lung cancer in humans. Alternative reasons for this difference might include: (a) black men smoke different brands of cigarettes than white men; (b) black men smoke a cigarette more completely than white men; (c) blacks have a 12%-14% smaller vital capacity than whites; and (d) there might be significant differences in age distributions of the black and white smoking populations. A rebuttal to this criticism is given. (6 refs)

- 79-5496 Cancer Mortality Among Low-Risk Populations. (Eng) Enstrom, J. E. (Cancer Epidemiology, UCLA Sch. Public Health, UCLA, Los Angeles, CA). *UCLA Cancer Cent Bull* 6(3): 3-7; 1979.

The cancer mortality experience among the major low-risk populations in the US is reviewed. Over an 8-yr period, the mortality rates for cancer sites related to cigarette smoking or alcohol consumption were extremely low among a group of 47,000 Seventh-Day Adventists living in California. In addition, the risk of death from cancers of the colon, stomach, and pancreas was about 60%-70% that of the general US population, and for women the risk of postmenopausal deaths from cancers of the breast, ovary, and uterus was significantly below that of the general population; dietary factors were suggested as possible reasons for these findings. Compared with US whites, the cancer mortality ratio among Mormons during 1968-1975 was 66% for men and 81% for women. The total cancer death rate among active Mormon men >35 yr old living in California is approx 50% that of US white men. The remaining life expectancy for these Mormons is 44.6 yr, 8 yr longer than that of US white men in 1970. The cancer death rates among Mormons were lower than those expected for all sites except the prostate and except for lymphomas and leukemias. Cancer mortality rates among US nonsmokers were 58%-76% lower than those for US whites. The most plausible explanation is that the lack of smoking per se reduces the total cancer rate by a substantial amount. Other factors that appear likely to have the greatest impact on cancer mortality are personal health habits, diet, socioeconomic status, and certain host factors related to aging. (10 refs)

- 79-5497 Socioeconomic Aspects of Lung Cancer. (Fre) Saracci, R. (Unite d'epidemiologie et de biostatistique, Centre international de recherche sur le cancer, 150 cours Albert Thomas, F-69372 Lyon Cedex, France). *Schweiz Med Wochenschr* 109(22): 820-824; 1979.

The lung cancer incidence and mortality rates in Switzerland are reviewed and compared with those in other industrialized nations. From 1970 to 1972, the annual incidence of lung cancer (per 10^5 subjects) in Geneva was 60.4 in men and 7.5 in women; the respective rates in Connecticut, Birmingham (England), and Hamburg were 77.1 and 11.5, 53.7 and 12.2, and 63.0 and 9.2. In 1972, the annual lung cancer mortality rate in Switzerland was 42.6/ 10^5 men and 4.1/ 10^5 women, similar to the rates in West Germany, the US, and Italy. (22 refs)

- 79-5498 The Case-Referent (Case-Control) Study in Occupational Health Epidemiology. (Eng) Axelson, O. (Dept. Occupational Medicine, Univ. Hosp., Linköping, Sweden). *Scand J Work Environ Health* 5(2): 91-99; 1979.

The case-referent type of study requires less extensive data acquisition than the cohort approach and can be used to determine relative risk and absolute mortality and morbidity rates. It is also possible with this method to study the etiologic influence of several exposures within the same series of cases and referents. However, there are many methodological pitfalls which can form a source of bias in a case-referent study. These include those relating to the role of exposure status in the selection of cases and/or referents, inaccuracy of the information on exposure among cases and referents, the possible relation of reference entity (usually various noncase diagnoses) to the exposure, and incomplete control of

confounding factors. Due to the close relationship between case-referent studies and proportional mortality studies, there is rarely a need for the proportional mortality approach. A study of arsenic as a possible cause of lung cancer and other types of malignancies and cardiovascular disease is given as an example of the case-referent method. (21 refs)

- 79-5499 Effect of Lead on Reproduction. (Hun) Peter, S. (Humangenetikai Laboratorium, Országos Kozegszegügyi Intezet, Budapest, Hungary); Czeizel, E. *Egeszsegudomány* 23(2): 180-187; 1979.

Studies of the effects of lead on reproduction are reviewed. Lead was found to have teratogenic effects in rats and golden hamsters and mutagenic effects in some experimental animals. No chromosome aberrations were seen in occupationally exposed subjects. (81 refs)

- 79-5500 Are Malignancies Increased in Uremia? (Eng) Kjellstrand, C. M. (Univ. Minnesota Hosps., Minneapolis, MN 55455). *Nephron* 23(4): 159-161; 1979.

Literature suggesting a possible relationship between uremia and malignancy is reviewed, and the types of neoplasms and the diagnoses of renal failure in 35 patients are listed. The most common cancer sites were the kidney (6 patients) and skin (5 patients). The most common types of renal failure were polycystic kidney disease (8 patients) and chronic pyelonephritis (6 patients). It seems probable that the incidence of malignancies is increased by chronic uremia and chronic hemodialysis. (24 refs)

- 79-5501 Pancreatic Cancer. An Overview of Epidemiology, Clinical Presentation, and Diagnosis. (Eng) Malagelada, J. R. (Gastroenterology Unit, Div. Gastroenterology and Internal Medicine, Mayo Clinic, Rochester, MN 55901). *Mayo Clin Proc* 54(7): 459-467; 1979.

The epidemiology, clinical presentation, and diagnosis of pancreatic cancer are reviewed. Pancreatic cancer is a common and lethal neoplasm whose etiological factors have not been identified. Pancreatic cancer is rarely diagnosed early. The most common prediagnosis symptoms are wt loss, abdominal pain, and jaundice, all of which may be symptoms of other malignant and nonmalignant diseases. Results of routine laboratory tests are often within normal limits, even in the presence of metastatic disease. Among the more invasive tests and imaging techniques that are being used are pancreatic function tests and pancreatic juice cytology, various techniques for visualizing the pancreas, and nonoperative biopsy techniques. A study of 70 patients suspected of having pancreatic cancer in whom routine diagnostic tests were negative showed that the endoscopic retrograde pancreatogram and arteriogram were the most sensitive and specific tests for detecting pancreatic cancer and differentiating between cancer and pancreatitis. Abdominal ultrasonography should be performed first when pancreatic cancer is suspected. If results are negative, pancreatic exocrine function tests should be done, and positive results from either procedure should be followed up with endoscopic retrograde pancreatography. (67 refs)

- 79-5502 Hepatic Cancers in Man: Quantitative Perspectives. (Eng) Popper, H. (Stratton Lab. Study Liver Diseases, Mount Sinai Sch. Medicine, City Univ. New York, New York, NY 10029). *Environ Res* 19(2): 482-494; 1979.

The worldwide distribution and incidence of malignant hepatic tumors (hepatocellular carcinoma, hepatoblastoma, intrahepatic bile duct carcinoma, and hepatic angiosarcoma) are reviewed, along with the etiologic factors involved. The geographic distribution of human hepatic malignancies strongly suggests a causative role of environmental factors. The vast majority of these malignancies in all areas of the world is usually associated with cirrhosis and one of three factors: hepatitis B infection, alcoholism, or aflatoxin exposure. The greatest chance for prevention lies in limiting hepatitis B infection. Although they constitute only a very small number of all hepatic malignancies, some tumors not associated with cirrhosis have been caused by industrial and therapeutic factors. A large number of environmental or industrial agents are carcinogenic in animals, but there is no conclusive evidence of their hepatocarcinogenicity in humans. Nevertheless, these substances may alter the hepatic metabolism with consequences for the liver and other organs. (93 refs)

- 79-5503 Role of Oral Contraceptive Agents in the Pathogenesis of Liver Tumors. (Eng) Nissen, E. D. (Univ. California, Coll. Medicine, Irvine, CA); Kent, D. R.; Nissen, S. E. *J Toxicol Environ Health* 5(2/3): 231-254; 1979.

Data from the Registry for Liver Tumors Associated with Oral Contraceptives on 90 women with liver tumors who had taken oral contraceptives are reviewed. More than 75% of the patients were <35 yr old. Most patients were exposed to mestranol (ME) alone or alternately with ethinylestradiol, both synthetic steroidal estrogens. Inability to demethylate ME in the smooth endoplasmic reticulum of hepatocytes may allow massive accumulation of oncogenic metabolites. This is probably a pharmacogenetic variable in a small number of women. Cholestasis, hypervascularity, induction of intracellular enzyme systems, thrombogenesis, and thickening of arterial and venous walls are other known effects of synthetic estrogens and progestogens. All may contribute to the pathogenesis of liver tumors. Many patients are asymptomatic until there is rapid expansion of the tumor. Pain occurs when Glisson's capsule stretches. Intrahepatic bleeding and liver rupture are common sequelae. Ligation of the hepatic artery may be lifesaving in the face of exsanguinating liver bleeding. Reports of regression with observation alone are encouraging. Instances of progression of unresected adenomas to rupture during subsequent pregnancy dictate avoidance of sex steroids in patients with hepatic neoplasia. Sonography, computerized axial tomography, radionuclide scans, and selective celiohepatic angiography are useful methods for the diagnosis of liver tumor in the symptomatic patient. There is a primary need to develop biochemical methods for detecting patients at risk for developing liver tumors. Epidemiologic research and central reporting of case histories are needed in the search for common factors. (17 refs)

- 79-5504 Proceedings of the Symposium: Early Gastric Cancer. (Eng) Kawai, K. (Dept. Preventive Medicine, Kyoto Prefectural Univ. Medicine, Kyoto, Japan); Misaki, F.; Kohli, Y.; Ida, K.; Ramirez Ramos, A. *Gastroenterol Jpn* 14(3): 266-271; 1979.

The occurrence and growth characteristics of gastric cancer in

humans are reviewed. Because the experimental gastric cancers induced in dogs with N-methyl- or N-ethyl-N'-nitro-N-nitrosoguanidine are dissimilar from those seen in humans, knowledge gained from animal experiments cannot be applied directly to human subjects. The incidence of gastric cancer is very high among the Japanese, and atrophic gastritis, which is almost always associated with intestinal metaplasia of the gastric mucosa, appears in younger age groups among the Japanese than among other populations. It appears that well-differentiated gastric carcinoma has a much closer relation to intestinal metaplasia than does undifferentiated cancer. The rate of malignant change in gastric ulcers appears to be very low. The doubling time of early gastric cancer varies with histologic type and depth of invasion, ranging from 2 to 10 yr in the depressed types that are most commonly encountered. Early gastric cancers with small diameters apparently grow slowly, whereas those with large diameters grow more rapidly. The change from early to advanced cancer involves a change from Borrmann type IIb to types IIc or IIc + III; some cases may go directly to Borrmann type IV. (6 refs)

- 79-5505 Cholesterol and Colon Cancer (Letter to Editor). (Eng) Cruse, P. (Surgical Unit, Rayne Inst., Univ. Coll. Hosp. and Medical Sch., London WC1E 6JJ, England); Lewin, M.; Clark, C. G. *Lancet* 2(8132): 43-44; 1979.

Information indicating that lack of dietary fiber plays no primary role in human colon carcinogenesis is reviewed, and nine publications that fail to substantiate the association of either colonic bacteria or increased fecal bile acids with colorectal cancer risk are cited. Evidence indicating that increased fecal cholesterol excretion and decreased fecal cholesterol degradation are related to colorectal cancer risk is presented. (26 refs)

- 79-5506 Food and Nutrition in the Netherlands; Fighting the Consequences of Prosperity. (Dut) Hautvast, J. G. (Vakgroep Humane Voeding, Landbouwhogeschool, Wageningen, Netherlands); Hermus, R. J. *Ned Tijdschr Geneesk* 123(22): 939-944; 1979.

The influence of current dietary habits on the incidence of cardiovascular diseases and cancer in the Netherlands is discussed. Current hypotheses (related to intractable constipation and small feces volume, high meat consumption, alterations of gallbladder metabolism) to explain the observed correlation between nutrition pattern and the incidence of colon cancer are briefly presented. (no refs)

- 79-5507 Epithelial Proliferative Disease of the Breast - A Marker of Increased Cancer Risk in Certain Age Groups. (Eng) Rogers, L. W. (Dept. Pathology, Carraway Methodist Hosp., Birmingham, AL); Page, D. L. *Breast* 5(2): 2-7; 1979.

The results of a 20-yr follow-up study of 925 women who had benign breast biopsies, and a survey of the literature suggest that certain histologic patterns of epithelial proliferative breast disease indicate an increased risk for subsequent mammary carcinoma. This risk in the follow-up study was four to six times that of the general population if atypical lobular hyperplasia was present and

two to three times if ductal hyperplasia was present in a patient >45 yr old. There was no increased risk if the patient was younger than 45 yr or if sclerosing adenosis was present. (13 refs)

- 79-5508 Pregnancy and Lactation in Relation to Breast Cancer Risk. (Eng) Vorherr, H. (Dept. Obstetrics-Gynecology and Pharmacology, Univ. New Mexico, Sch. Medicine, 915 Stanford Drive N.E., Albuquerque, NM 87131). *Semin Perinatol* 3(3): 299-311; 1979.

The effects of pregnancy and lactation on the risk of breast cancer (BC) are reviewed. Pregnancy early in life appears to protect against BC, with the prolonged periods of mitotic rest of the breast tissue during gestation and lactation and the increase in certain hormones (estriol and progesterone) having been suggested as potential mechanisms of protection. However, it is unlikely that estriol protects against BC. BC risk appears to be fourfold greater in women whose first pregnancy occurs after 30-35 yr of age than in nulliparous women of the same age group. However, the assumption of a protective effect of early pregnancy and the deleterious effect of late pregnancy is not uniformly agreed upon. The clearance of mammary carcinogens via the milk, mitotic rest, and nutritional and immunologic factors have been suggested as potential mechanisms of the protective effect of nursing. Some investigators believe that lactation has little or no effect on BC risk. In a certain strain of mice, a mammary RNA-type tumor virus is transmitted through the milk and causes adenocarcinoma in almost all offspring. About 10%-20% of lactating women have viruslike particles with RNA-dependent DNA polymerase activity in their milk. A specific relationship between mouse mammary tumor virus and these particles has been suggested, although some researchers suggest that the "virus" particles in human milk are only artifacts. The possible role of prolactin in the development and maintenance of human BC is questioned. (118 refs)

- 79-5509 Teenagers and Contraception. (Eng) Rozenbaum, H. (15 Rue Daru, 75008 Paris, France). *Int J Gynaecol Obstet* 16(6): 564-567; 1979.

Among the factors physicians should take into account when prescribing contraceptives for teenagers are cytologic abnormalities in young women. One study showed that the incidence of cervical dysplasia (20%) in girls under 19 yr of age has increased five times since 1971. In two other studies, the incidences of cytologic abnormalities in young women were 1.7% and 4.8%, respectively. The risk of cervical cancer seems to be associated with low socioeconomic level, sexual intercourse at an early age and a diversity of partners, and herpes simplex virus type 2 infection. (13 refs)

- 79-5510 Discussion Summary on Measurement of Carcinogenic Risk. (Eng) Davis, W. (Res. Training and Liaison Unit, International Agency Res. Cancer, 150 cours Albert Thomas, 69372 Lyon Cedex 2, France); Rosenfeld, C. *IARC Sci Publ* (25): 229-233; 1979.

A discussion of the measurement of carcinogenic risk is summariz-

ed. In order to compare carcinogens, common units have to be agreed upon. However, there is no obvious correlation between a dose of radiation and the dose generated in vivo from a chemical carcinogen in which reactive electrophiles must be generated in situ from the small proportion of the dose that reaches the target organ or tissue. In addition, mixed or sequential exposures occur. Insufficient work has been done on summation of risks. In doing so, substances should be considered in one of two categories: (1) those acting through direct interference with the genetic system (for which a no-toxic-effect level cannot be accepted) and (2) those acting in other ways (for which no-toxic-effect levels ought to be set). Although there are several mathematical models for calculating risk based on the extrapolation from high doses given to animals to the much lower doses that constitute human exposure, none have been accepted, and the validity of such extrapolations is uncertain. Experiments should be large enough to establish upper confidence limits on the dose required to induce cancer or to give wt to a negative result. Confidence limits should be included in all experimental and epidemiological reports. A variety of animal species and strains must be studied to determine which most resemble humans in susceptibility to a wide range of carcinogens. An important distinction between animal experiments and human observations is time: the former are generally predictive, whereas the latter are generally retrospective. Negative epidemiological findings in humans are important, because human observations take into account such factors as biological availability of the potential carcinogen in the environment. Among the many difficulties in the interpretation of epidemiological data, however, are the quantification of exposures and the computation of expected numbers. It is unclear what wt should be given to studies in which only benign tumors are found. More attention must be paid to en-

vironmental pollutants and their interactions in evaluating cancer risk. (no refs)

- 79-5511 Biochemical Regulators of Bone Resorption and Their Significance in Cancer. (Eng) Martin, T. J. (Dept. Medicine, Univ. Melbourne, Victoria 3081, Australia); Atkins, D. *Essays Med Biochem* 4: 49-82; 1979.

The biochemical regulators of bone resorption are reviewed, along with their significance in cancer. Cancer patients can be classified into four main groups: those with hypercalcemia (HC) in association with a nonparathyroid neoplasm that has not metastasized to bone (Group I); those with HC in association with metastatic cancer growth in bone (Group II); those with metastatic cancer in bone but without HC (Group III); and those with HC in association with multiple myeloma, lymphoma, or leukemia (Group IV). The major known humoral influences on bone resorption are parathyrin, prostaglandins, osteoclast-activating factor, vitamin D, osteolytic sterols, and calcitonin. There are valid arguments against the hypothesis that Group I cancers are related to parathyrin, and it appears that most such patients have HC caused by some other humoral factor. HC in some animal syndromes appears to be due to the production of a prostaglandin by tumor cells, and prostaglandins may have a role in the establishment of bony metastases and in the promotion of osteoclastic resorption around the sites of established metastases. Osteoclast-activating factor or some related agent appears more likely to be involved in Group IV cases than prostaglandins. The relationships, if any, of vitamin D, osteolytic sterols, and calcitonin to HC in malignancy have not been demonstrated. (123 refs)

CHEMICAL CARCINOGENESIS

- 79-5512 Chromosome Studies in Patients Treated with Chemotherapy for Trophoblastic Tumours. (Eng) Lawler, S. D. (Dept. Cytogenetics and Immunology, Royal Marsden Hosp., Fulham Rd., London, SW3 6JJ, England); Walden, P. A. In: *Mutagen-Induced Chromosome Damage in Man. Proceedings of a Symposium held in Edinburgh, Scotland, July 7-8, 1977*. Medical Research Council (Edinburgh, Scotland): 355 pp.; 239-246; 1978.

Lymphocyte and bone marrow chromosomes of patients treated by chemotherapy for trophoblastic tumors were monitored for the frequency of aberrations before, during, or after treatment. The patients were selected from three groups: low risk, medium risk and high risk. The patients in the low-risk group showed no evidence of a damaging effect of therapy (methotrexate + folinic acid) on the chromosomes of the lymphocytes. Those in the medium-risk group showed increased chromosome damage following therapy, (methotrexate + seven other drugs), but the increase was not judged sufficient to cause concern. Patients on intensive therapy (seven or eight drugs + radiotherapy) showed a very high frequency of chromosome damage in their lymphocytes. Damage to bone marrow chromosomes was unremarkable in all groups. In general, survivors showed little evidence of genetic damage to somatic cells. (11 refs)

- 79-5513 Cytogenetic Effects of Chemotherapy and Cranial Irradiation on the Peripheral Blood Lymphocytes of Children with Leukaemia. (Eng) Fischer, P. (Inst. Cancer Res., Univ. Vienna, Borschkegasse 8a, A 1090 Vienna, Austria); Nacheva, E.; Pohl-Ruling, J.; Krepler, P. In: *Mutagen-Induced Chromosome Damage in Man. Proceedings of a Symposium held in Edinburgh, Scotland, July 7-8, 1977*. Medical Research Council (Edinburgh, Scotland): 355 pp.; 247-257; 1978.

Children with leukemia were compared with children treated for nonmalignant disease in order to determine if there is an increased tendency to breakage in the normal chromosomes of leukemic children and whether treatment, particularly cranial irradiation, produces chromosome aberrations. The leukemia group (34 children aged 3-11 yr) included 32 children with acute lymphocytic leukemia (ALL), 30 of whom had received cranial irradiation (2,400 rads) in addition to intensive chemotherapy; the 2 other children, one with acute myeloid leukemia (AML) and one with chronic myeloid leukemia (CML), had had chemotherapy only. The nonmalignant (NM) group consisted of 18 children, aged 2-14 yr, all with nephrosis; 9 were on cortisone treatment alone and 9 cortisone-resistant patients were treated with additional chemotherapy. The chromatid aberration rate of the leukemia group prior to treatment did not differ significantly from that of the NM group (4.1% gaps, 0.8% breaks). Cells from the ALL group and the AML and CML patients, analyzed 1.2, 8.3, and 46 mo after the start of chemotherapy, showed steady increase in gaps (mean values of 5.9, 7.3, and 12.0%), but rates of breaks in chromatids fluctuated (3.4% at 1.2 mo, 1% at 8.3 mo, 5.3% at 46 mo). Two-break aberrations (dicentrics and minutes) appeared only after 36 mo of chemotherapy. The cells from ALL patients treated with cranial irradiation showed decreased chromatid aberration rates immediately after irradiation (4.4% gaps and 1.4% breaks as against 5.9% gaps and 3.4% breaks in patients prior to

radiation). Chromosome aberrations of both types were present at all periods. The following conclusions were reached: (1) prolonged, intensive chemotherapy causes a significant rise in chromatid aberrations, both gaps and breaks; (2) after 2 yr of treatment, chemotherapy alone causes a small, significant increase in chromosome breaks; (3) radiation of 2,400 rads to the cranial area and medulla oblongata causes an immediate, sharp rise in chromosome aberrations and concurrent drop in chromatid aberrations. No evidence of an increased, spontaneous breakage rate in the normal chromosomes of leukemic children was found. (26 refs)

- 79-5514 Toxic and Mutagenic Effects of Carcinogens on the Mitochondria of *Saccharomyces cerevisiae*. (Eng) Egilsson, V. (Dept. Botany and Microbiology, Univ. Coll. London, Gower St., London WC1E 6BT, England); Evans, I. H.; Wilkie, D. *Mol Gen Genet* 174(1): 39-46; 1979.

Nineteen haploid yeast (*Saccharomyces cerevisiae*) strains were used to assess the relative growth inhibitory potencies on fermentable vs nonfermentable media of a series of carcinogenic and noncarcinogenic chemicals. The majority of the carcinogens were distinctly more potent on the nonfermentable (glycerol) medium, where mitochondrial function was required for growth, than on the fermentable medium, where it was not. The antimitochondrial selectivity indicated by these growth tests was much less for the noncarcinogens. Similarly, most carcinogens induced the cytoplasmic petite mutation, whereas the noncarcinogens did not. Five carcinogens impaired the development of cytochromes *aa₃* and *b* in glucose cultures. Six carcinogens inhibited growth on three fermentable sugars, the utilization of which requires mitochondrial function. Of five carcinogens examined, four suppressed the surface-dependent phenomenon of flocculence in a flocculating strain of yeast at concentrations primarily affecting the mitochondrial system. The fifth carcinogen had a similar but less pronounced effect. (45 refs)

- 79-5515 Synthesis of the Glucuronic Acid Conjugate of Methylazoxymethanol. (Eng) Matsumoto, H. (Dept. Agricultural Biochemistry, Univ. Hawaii, 1800 East-West Road, Honolulu, HI 96822); Takata, R. H.; Komeiji, D. Y. *Cancer Res* 39(8): 3070-3073; 1979.

The synthesis of methylazoxymethyl- β -D-glucopyranosiduronic acid (MAM-GlcUA), its physical and biochemical properties, and its acute toxicity and mutagenicity are described. MAM-GlcUA was synthesized by oxidizing the primary alcohol of the glucose moiety of cycasin (methylazoxymethanol- β -D-glycopyranoside) to a carboxylic acid. The oxidation was carried out by bubbling oxygen gas through a cycasin soln in the presence of a platinum-on-carbon catalyst. A band at $1,715\text{ cm}^{-1}$, not present in the cycasin infrared spectrum, appeared in the spectrum of the oxidized cycasin product, establishing the presence of a carboxylic acid group. The oxidation product was MAM-GlcUA, because when it was hydrolyzed with *Escherichia coli* β -glucuronidase, it produced methylazoxymethanol and glucuronic acid. In addition, the β -glycosidic linkage of cycasin was retained. When varying quan-

ties of the synthesized MAM-GlcUA were injected into Wistar rats of both sexes and of varying wts, they were not acutely toxic. The compound was mutagenic to *Salmonella typhimurium* when preincubated with *E. coli* β -glucuronidase, but not when it was preincubated with bovine liver glucuronidase. (19 refs)

- 79-5516 Inhibitory Effects of Butylated Hydroxyanisole on Methylazoxymethanol Acetate-induced Neoplasia of the Large Intestine and on Nicotinamide Adenine Dinucleotide-dependent Alcohol Dehydrogenase Activity in Mice. (Eng) Wattenberg, L. W. (Dept. Lab. Medicine and Pathology, Univ. Minnesota, Minneapolis, MN 55455); Sporn, V. L. *J Natl Cancer Inst* 63(1): 219-222; 1979.

A study was carried out to determine whether butylated hydroxyanisole (BHA), an antioxidant food additive, could inhibit methylazoxymethanol acetate (MAM acetate)-induced large-bowel carcinogenesis in female CF₁ mice. Mice of 8 or 11 wk of age received diets containing 5 or 10 mg BHA/g diet and sc injections of MAM acetate (0.3 mg 2x/wk for 3 wk or 0.2 mg 2x/wk for 3 wk followed by 0.3 mg 2x/wk for 3 wk). BHA was added to the diet 9 days before the first injection of MAM acetate and withdrawn 1 day after the final injection. Mice were sacrificed and autopsied at 46 or 51 wk of age. Approx 40% of 72 control mice given only MAM acetate developed large intestinal adenomas and/or adenocarcinomas, whereas only 5% of 39 mice receiving the 5-mg/g BHA diet and none of 17 mice receiving the 10-mg/g BHA diet developed these neoplasms. The inhibitory effects of BHA [0.01-2.0 micromoles (μ mol)/ml reaction mixture] on the activity of unpurified liver and large intestine NAD⁺-dependent alcohol dehydrogenase (a postulated activating enzyme for MAM acetate), using a substrate concentration of 16 μ mol/ml reaction mixture, were not concentration-dependent: 0.5 μ mol BHA reduced the activity to 34%-56% of control levels, but higher BHA concentrations resulted in little additional inhibition. These results suggest that more than one protein catalyzes the alcohol dehydrogenase reaction. The parallel finding of BHA inhibition of MAM acetate carcinogenesis of the large bowel and of NAD⁺-dependent dehydrogenase activity supports the postulated role of the dehydrogenase activity in activating MAM to an ultimate carcinogenic form. However, BHA has multiple biologic actions, so that its inhibitory effect on MAM acetate-induced neoplasia of the large intestine may entail some other mechanism. (14 refs)

- 79-5517 Mechanism of Inhibition of Hepatic Protein Synthesis in Rats by the Carcinogen, Methylazoxymethanol Acetate. (Eng) Grab, D. J. (Dept. Cell Biology, Rockefeller Univ., 1230 York Ave., New York, NY 10021); Pavlovic, A.; Hamilton, M. G.; Zedeck, M. S. *Biochim Biophys Acta* 563(1): 240-252; 1979.

Weanling male Sprague-Dawley rats were used to determine which of the components necessary for hepatic protein synthesis are affected by the potent carcinogen methylazoxymethanol acetate (MAMA). Incubation of microsomes and the high speed supernatant fraction from livers of rats treated 1 hr previously with MAMA (35 or 70 mg/kg) resulted in an approx 67% and 77% inhibition, respectively, of L-(4,5-³H)leucine incorporation into protein. Fractions from the livers of rats treated with dimethylnitrosamine (DMN, 30mg/kg) were inhibited by 50%. Both MAMA and DMN appeared to act at the level of the polysome. Free polysomes were isolated from the livers of rats 1 hr after treatment with 70 mg/kg MAMA. After 30 min incubation,

when protein synthesis had ceased to be linear, the free, membrane-derived and membrane-bound polysomes were each inhibited by approx 40%-50%. MAMA disaggregated the polysomes to lighter polysome species. Poly(U)-directed polyphenylalanine synthesis by native ribosomal subunits was greater in preparations isolated from rats treated with carcinogen than in saline-treated controls. Moreover, the native ribosomal subunit fraction from treated livers was able to synthesize a protein similar in mol wt to globin in response to added rabbit globin messenger RNA (mRNA). These studies show that MAMA does not induce significant alterations in ribosomal subunits or initiation factors and suggest that the inhibition of protein synthesis and disaggregation of polysomes may result from an alteration in cytoplasmic mRNA or from the association of this mRNA with ribosomes. - 79-5518 Environmental Factors Affecting Monooxygenase Activity of Microsomal Fractions of Human Liver Biopsies (Meeting Abstract). (Eng) Boobis, A. R. (Dept. Clinical Pharmacology, Royal Postgraduate Medical Sch., Hammersmith Hosp., London W12 0HS, England); Brodie, M. J.; Bulpitt, C. J.; Davies, D. S. *Br J Pharmacol* 66(3): 426P-427P; 1979 (1 ref)

- 79-5519 Role of Pesticides in Hepatocarcinogenesis. (Eng) Sugar, J. (Res. Inst. Oncopathology, Budapest, Hungary); Toth, K.; Csuka, O.; Gati, E.; Somfai-Relle, S. *J Toxicol Environ Health* 5(2/3): 183-191; 1979.

The carcinogenicity of the herbicide 2,4,5-trichlorophenoxyethanol (TCPE), which is contaminated with 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD), was tested in Swiss mice. Doses of 0.7-70.0 mg/kg TCPE containing 0.0007-0.007 μ g/kg TCDD were administered by gastric intubation once a week over a period of 1 yr. The incidence of liver tumors was doubled only in males given the two highest doses of TCPE (67.0 and 70 mg/kg: the tumor incidence was 48% and 58%, respectively, compared with 26% in controls. Reduction of the TCPE and TCDD doses to 1/10 and 1/100 of the max tolerated dose resulted in a reduced incidence of liver tumors to levels similar to that of controls. When two groups of mice were given the same dose of TCPE but hundredfold different doses of TCDD, no significant differences in the incidence of liver tumors resulted, indicating that TCDD in this dose range (0.0007-0.07 μ g/kg) did not influence tumor frequency and that TCPE was responsible for the tumor-enhancing effect. There was no predominance of any histological type of hepatocellular tumor, and cirrhosis never preceded tumor development. When the in vivo data were compared with data on the induction of microsomal aryl hydrocarbon hydroxylase and biphenyl 2-hydroxylase activities by TCPE and TCDD, there was no correlation between the carcinogenicity of the drugs and their ability to induce these two enzymes. (26 refs)

- 79-5520 Research Related to the Herbicide Buvinol, Especially for Possible Carcinogenicity. (Eng) Sugar, J. (Res. Inst. Oncopathology, Budapest, Hungary); Toth, K.; Somfai-Relle, S.; Bence, J. *IARC Sci Publ* (25): 167-172; 1979.

The toxicity and carcinogenicity of the new herbicide Buvinol, which contains 2,4,5-trichlorophenoxyethanol (TCPE), were evaluated in male and female Swiss mice. In long-term carcinogenicity tests, the po administration of the max tolerated dose (70 mg/kg) of TCPE, contaminated with 0.1 ppm 2,3,7,8-

tetrachlorodibenzo- p-dioxin (dioxin), increased the incidence of liver tumors in male mice; lower doses of TCPE (7.0 and 0.7 mg/kg) and dioxin did not influence tumor frequency. The tumors induced by 70 mg/kg TCPE + 0.1 ppm dioxin included 71 hepatomas, 34 hepatocellular carcinomas, and 5 cholangiohepatocellular carcinomas. Exposure of workers to TCPE during its production or use should be controlled and reduced. (8 refs)

- 79-5521 The Effect of Ethylene Dibromide on Differentiation of the Acrosome, Nucleus, and Transient Nuclear Appendages in Ram Spermatids. (Eng) Hrudka, F. (Dept. Veterinary Anatomy, Western Coll. Veterinary Medicine, Univ. Saskatchewan, Saskatoon, Saskatchewan, Canada S7N 0W0); ElJack, A. H. *J Ultrastruct Res* 67(2): 135-151; 1979.

The testes of Colombia rams treated with ethylene dibromide (EDB: 13.5 mg/kg/day sc, for 12 days) and castrated 22, 27, 32, or 38 days after treatment were studied histologically and electron microscopically. The EDB treatment disturbed the differentiation of the acrosome, nucleus, and transient nuclear appendages. The prime target was the acrosome, which was hit first and most during its growing phase, ie, the cap phase of spermiogenesis. The results were aplasia, hypoplasia, or hyperplasia; deformation of the acrosomic cap; vesicular inclusions of the acrosomic matrix; and lesions in the acrosome attachment to the nucleus. Some of these anomalies could be related to the aberrant morphology and activity of the Golgi complex. The drug also affected nuclear metamorphosis taking place in the third phase of spermiogenesis. The effect was expressed in abnormal chromatin condensation, disturbed sap elimination, and deviation from modal shaping. It is postulated that the nuclear metamorphosis is supported by a machinery consisting of the acrosome, caudal manchette, and Sertoli cell mantle. The acrosome assumes the key position, since it seems to be the prerequisite for cell polarization and the polarization essential for differentiation of the caudal manchette and Sertoli cell mantle. The absence of the acrosome accounted for the complete failure of nuclear shaping, but the lack of the other appendages accounted for a partial deviation from the modal nuclear shape. (25 refs)

- 79-5522 Pattern and Dynamics of Teratospermia Induced in Rams by Parenteral Treatment with Ethylene Dibromide. (Eng) ElJack, A. H. (Dept. Veterinary Anatomy, Coll. Veterinary Medicine, Ohio State Univ., Columbus, OH 43210); Hrudka, F. *J Ultrastruct Res* 67(2): 124-134; 1979.

The pattern and dynamics of the transient teratospermia induced in Colombia rams with ethylene dibromide (EDB: 7.8-13.5 mg/kg/day sc, for 12 days) were studied. Cytological, cytochemical, and electron microscopic investigations were made of ejaculated sperm before, during, and after treatment until full recovery. The teratospermia had a relatively constant pattern and was dose-dependent, although individual animals varied in susceptibility. It was preceded by a latent period of about 4 wk, reached its max between 9 and 12 wk, and dissipated between 14 and 16 wk after the start of treatment. EDB strongly inhibited motility and reduced the activity of nitroblue tetrazolium reductase, but there were no corresponding changes in tail morphology. Structural aberrations were found in order of decreasing frequency in the acrosome, nucleus, and mitochondrial sheath. (27 refs)

- 79-5523 Effects of Methylene Chloride, Trichloroethane, Trichloroethylene, Tetrachloroethylene and Toluene

on the Development of Chick Embryos. (Eng) Elovaara, E. (Dept. Industrial Hygiene and Toxicology, Inst. Occupational Health, Haartmaninkau 1, SF-00290 Helsinki 29, Finland); Hemminki, K.; Vainio, H. *Toxicology* 12(2): 111-119; 1979.

The approximate LD₅₀ for trichloroethylene and trichloroethanes when determined 14 days after injection into the air space of fertilized chicken eggs (at 2, 3, and 6 days incubation) varied between 50 and 100 µmol/egg, and LD₅₀ for toluene, tetrachloroethylene, and methylene chloride were over 100 µmol/egg. These chemicals induced macroscopic malformations at doses of 5-100 µmol/egg. The teratogenic potential of the tested compounds decreased in the following order: 1,1,1-trichloroethane > trichloroethylene > methylene chloride, tetrachloroethylene, 1,1,2-trichloroethane > toluene. (23 refs)

- 79-5524 Mutagenicity Studies with Halothane in *Drosophila Melanogaster*. (Eng) Kramers, P. G. (Natl. Inst. Public Health, P.O. Box 1, Bilthoven, Netherlands); Burm, A. G. *Anesthesiology* 50(6): 510-513; 1979.

The ability of halothane (HT) to induce sex-linked recessive lethal mutations in *Drosophila melanogaster* was investigated. Adult male flies were exposed to 1,000 or 1,600 ppm (volume/volume) HT for 14 days or to 2,100 or 20,000 ppm HT for 1 or 2 days. In several experiments, mutation frequency was increased slightly. Pooled data from the 14-day experiments indicated that the increase was twice the spontaneous rate, just reaching 5% significance level. This was considered a borderline result, indicating, with a fair degree of probability, that HT has weak mutagenic activity under the conditions studied. (23 refs)

- 79-5525 Carcinogenicity of Halothane in Swiss/ICR Mice. (Eng) Baden, J. M. (Anesthesiology Service-112A, VA Hosp., 3801 Miranda Ave., Palo Alto, CA 94304); Mazze, R. I.; Wharton, R. S.; Rice, S. A.; Kosek, J. C. *Anesthesiology* 51(1): 20-26; 1979.

A simplified in vivo bioassay system was used to test the carcinogenicity of halothane (HT) in Swiss/ICR mice. HT was tested only at its max tolerated dose, and histologic examination was performed only on tumor masses and other grossly abnormal tissues found at necropsy. Two groups of 15 timed pregnant mice were exposed to 500 ppm (0.05%) HT or to compressed air for 2 hr on days 10-19 of pregnancy. Five days after birth, the offspring were similarly exposed three times weekly for 78 wk. After a 10-wk no-treatment observation period, all remaining mice were examined by necropsy. Mice dying or killed *in extremis* before final sacrifice at 88 wk of age also underwent complete gross necropsy, unless extensive cannibalism or autolysis precluded examination. The incidences of malignant tumors, hepatomas/hepatic nodular hyperplasias, and benign tumors in HT-treated mice were 7%, 6%, and 20%, respectively; there were similar incidences of these lesions in control animals. It is concluded that, under the conditions of this experiment, lifetime administration of HT at its max tolerated dose is not associated with an increased incidence of neoplasia in Swiss/ICR mice. (14 refs)

- 79-5526 Metabolic and Mutagenicity Studies on DDT and 15 Derivatives. Detection of 1,1-Bis(p-chlorophenyl)-

2,2-dichloroethane and 1,1-Bis(*p*-chlorophenyl)-2, 2, 2-trichloroethyl Acetate (Kelthane Acetate) as Mutagens in *Salmonella Typhimurium* and of 1,1-Bis(*p*-chlorophenyl) Ethylene Oxide, a Likely Metabolite, as an Alkylating Agent. (Eng) Planche, G. (Unit Chemical Carcinogenesis, Internatl. Agency Res. Cancer, 150 cours Albert-Thomas, 69372 Lyon, France); Croisy, A.; Malaveille, C.; Tomatis, L.; Bartsch, H. *Chem Biol Interact* 25(2/3): 157-175; 1979.

Using a novel in vitro technique whereby microsomal enzymes were embedded in an agar layer to prolong their viability, 1,1-bis(*p*-chlorophenyl)ethylene, a mammalian metabolite of 1,1-bis(*p*-chlorophenyl)-2, 2, 2-trichloroethane (DDT), was converted by microsomal monooxygenases of mouse liver into 1,1-bis(*p*-chlorophenyl)-1,2-ethanediol. The putative epoxide intermediate 1,1-bis(*p*-chlorophenyl)ethylene oxide, a new compound, was synthesized; it showed weak alkylating activity with 4-(4-nitrobenzyl)pyridine but was not mutagenic in *Salmonella typhimurium* strains TA100 and TA98. DDT and 13 of its metabolites or putative synthetic derivatives, including 1,1-bis(*p*-chlorophenyl)-2,2-dichloroethylene, 1,1-bis(*p*-chlorophenyl)-2-chloroethylene, 1,1-bis(*p*-chlorophenyl)-2-chloroethane, 2,2-bis(*p*-chlorophenyl)ethanol, bis(*p*-chlorophenyl)acetic acid, and 1,1-bis(*p*-chlorophenyl)-2,2,2-trichloroethanol (Kelthane), caused no mutagenic effects in *S. typhimurium* strains TA100 or TA98, either in the presence or absence of a mouse-liver microsomal fraction. 1,1-Bis(*p*-chlorophenyl)-2,2,2-trichloroethyl acetate (Kelthane acetate) was a direct-acting mutagen in strain TA100, whereas 1,1-bis(*p*-chlorophenyl)-2,2-dichloroethane was mutagenic in TA98, only in the presence of a mouse-liver microsomal system. The results are discussed in relation to possible pathways whereby DDT is converted to mutagenic and/or carcinogenic metabolites. (48 refs)

79-5527 Risk of Angiosarcoma in Workers Exposed to Vinyl Chloride as Predicted from Studies in Rats. (Eng) Gehring, P. J. (Toxicology Res. Lab., Dow Chemical, Midland, MI 48640); Watanabe, P. G.; Park, C. N. *Toxicol Appl Pharmacol* 49(1): 15-21; 1979.

Dose-response data for the induction of angiosarcoma in rats exposed to various levels of vinyl chloride (VC) together with attendant biotransformation data were used to estimate the risk of developing angiosarcoma in persons exposed to VC. Since a biotransformation product of VC, not VC per se, is responsible for the induction of angiosarcoma, the body surface area of people relative to rats was used to estimate the dose of the carcinogen biotransformed from VC by the former. Four models were used to extrapolate the data. Using a probit model, 10 hepatic angiosarcomas were predicted to occur in a recently reported epidemiological cohort of 9,677 workers; in actuality, five have occurred. Linear models and a model based on the equation, Risk = $1 - e(-\beta x)$, where x = dose, do not appear as reliable. For an 8-hr day, 5 days/week, 35-year time-weighted-average exposure of 1 ppm, the predicted incidence of hepatic angiosarcoma using the probit model is 1.5×10^{-6} . (16 refs)

79-5528 Vinyl Chloride and Trichloroethylene: Comparison of Alkylating Effects of Metabolites and Induction of Preneoplastic Enzyme Deficiencies in Rat Liver. (Eng) Laib, R. J. (Institut für Toxikologie, Universität Tübingen, Wilhelmstrasse 74, D-7400 Tübingen, W. Germany); Stockle, G.; Bolt, H. M.;

Kunz, W. *J Cancer Res Clin Oncol* 94(2): 139-147; 1979.

The extent of alkylation of nucleic acid by metabolites of trichloroethylene (TCE) and vinyl chloride (VC) was compared, along with the induction, by TCE and VC, of preneoplastic foci deficient in nucleoside-5-triphosphatase in newborn Wistar rats. [$1,2-^{14}\text{C}$]VC and [$1,2-^{14}\text{C}$]TCE were incubated with rat liver microsomes, NADPH, and yeast RNA. TCE metabolites were irreversibly bound to proteins in microsomal incubations to a higher extent than VC metabolites, but irreversible binding to RNA was lower for TCE metabolites. Hydrolysis of the RNA that was reisolated from microsomal incubations with ^{14}C -VC or ^{14}C -TCE and separation of the nucleosides showed different alkylation products arising from VC and from TCE. 1,N⁶-Ethenoadenosine and 3,N⁴-ethenocytidine were produced only with metabolites of VC, possibly through the formation of an imidazol ring. The different reactivities of VC and TCE metabolites prompted a comparison of the oncogenic effects of both compounds in rat liver cells. Newborn rats were exposed for 10 wk to 2,000 ppm VC or TCE 8 hr/day, 5 days/wk. After this period, livers of the animals were stained for nucleoside-5-triphosphatase. The VC-exposed rats showed focal hepatocellular deficiencies in this enzyme, which are supposed to represent an early sign of malignancy; no such changes were induced by TCE exposure. The data therefore suggest differences between the activity of VC and TCE in the rat liver. (24 refs)

79-5529 The effects of 1,1-Di(*p*-chlorophenyl)-2-chloroethylene on Plasma Enzymes and Blood Constituents in the Japanese Quail. (Eng) Westlake, G. E. (Pest Infestation Control Lab., Ministry Agriculture, Fisheries and Food, Tolworth, Surbiton, Surrey, KT6 7NF, England); Bunyan, P. J.; Stanley, P. I.; Walker, C. H. *Chem Biol Interact* 25(2/3): 197-210; 1979.

Glutamate oxaloacetate transaminase (GOT), glutamate dehydrogenase (GDH), sorbitol dehydrogenase (SDH), pseudo-cholinesterase (ChE) and various blood constituents were measured in the plasma of Japanese quail fed 1,1-di(*p*-chlorophenyl)-2-chloroethylene (DDMU) at low levels (50, 100, and 150 ppm) for periods ranging from 2 to 32 days. Previous work has shown that DDMU is a potent inducer of hepatic microsomal enzymes causing marked structural changes in the liver. A rapid increase in plasma GOT was observed within 4 days, accompanied by an increase in relative liver weight. Plasma GDH and SDH increased to a maximum between 16 and 24 days, suggesting an association with hepatic cell proliferation. Plasma ChE showed a steady increase over the time course of DDMU administration. The level of plasma lipid was reduced after 4 days, whereas the hepatic lipid content was substantially increased; thus the fatty liver condition may be caused by decreased release of triglyceride from the liver. Plasma glucose was reduced at 8 days, but there was no evidence of a hyperglycemic state. The changes noted after 2 days of DDMU diet were confirmed by measurements on birds 18 hr after oral dosing with DDMU (20, 100, 350, and 1,000 mg/kg body wt). The study demonstrates the values of plasma enzyme measurements for the early detection of toxic effects and indicates that DDMU administration leads to extrahepatic effects in addition to those previously described in the liver. 79-5530 Sensitivity of Human Lymphocyte Chromosomes to Ethylenimine Derivatives at Different Periods During

Cell Culture. (Eng) Bochkov, N. P. (Inst. Medical Genetics, Kashirskoye Shosse 6a, 115478 Moscow, USSR); Yakovenko, K. N. In: *Mutagen-induced Chromosome Damage in Man. Proceedings of a Symposium held in Edinburgh, Scotland, July 7-8, 1977.* Medical Research Council (Edinburgh, Scotland): 355 pp.; 290-299; 1978.

The dependence of chromosome aberration frequency in unstimulated cultures of human lymphocytes on the time of addition of four ethylenimine derivatives, phosphamide (60 µg/ml), thiophosphamide (20 and 30 µg/ml), dipine (40 µg/ml), and fotrin (40 µg/ml), was investigated. The four mutagens differed with respect to number of alkylating groups and number of active mutagenic centers. The chemicals were added to separate cultures every 4 hr from culture initiation (zero time) to 104 hr. The duration of exposure was 1 hr. The cells were harvested after 56-108 hr of culture. The mutagens were cytogenetically effective at all stages of the cell cycle. Max sensitivity was observed at 28-32 hr of culture, ie, 24-28 hr before harvesting, except for cultures exposed to dipin, in which sensitivity was practically constant from 0 to 32 hr. Thereafter, the sensitivity of the chromosomes to all the mutagens sharply decreased and reached a minimum at 48-52 hr. With thiophosphamide, the time of exposure vs effect curves had the same shape, independent of harvesting time, and they were described by a fourth-order polynomial. In contrast, the time of harvesting vs effect curves had essentially different shapes, depending upon the time of mutagen action. For assaying mutagenicity in terms of chromosome aberrations, consideration should be given to two indices of the mitotic cycle. The first indicates what mitotic cycle after stimulation the cell is in at the moment of exposure to a mutagen; the second is the mitotic cycle the cell is in at the moment of harvesting. (10 refs)

79-5531 Renal Carcinogenic and Nephrotoxic Effects of the Flame Retardant Tris(2,3-dibromopropyl) Phosphate in F344 Rats and (C57BL/6N x C3H/HeN)F₁ Mice. (Eng) Reznik, G. (Tumor Pathology Branch, Carcinogenesis Testing Program, NCI, NIH, Div. Cancer Cause and Prevention, Bethesda, MD 20014); Ward, J. M.; Hardisty, J. F.; Russfield, A. *J Natl Cancer Inst* 63(1): 205-212; 1979.

The pathology of the kidneys in rats and mice administered high and low dose of the flame retardant tris(2,3-dibromopropyl) phosphate (TBP) is described in detail. TBP was administered in the feed of 55 male and 55 female inbred F344 rats (100 or 50 ppm) rats and 50 male and 50 female (C57BL/6N x C3H/HeN)F₁ mice. (1,000 or 500 ppm). For each rodent type, 55 animals of each sex were used as controls. In treated male and female rats and mice, renal epithelial tumors developed at significant incidences. These tumors included renal tubular cell adenomas and carcinomas that developed from the proximal convoluted tubular epithelium. Among female mice and rats, hyperplasia and/or dysplasia of the proximal convoluted tubular epithelium with or without cystic dilatation of the tubules and increases in the size of cell nuclei were dose-dependent and recognized as preneoplastic and/or toxic lesions. The comparative histogenesis of renal tubular neoplasms is surveyed. (37 refs)

79-5532 Hepatic and Extrahepatic Induction of Drug-metabolizing Enzymes in Specific Pathogen Free and Germ Free Rats. (Eng) Hietanen, E. (Dept. Physiology, Univ. Kuopio, SF 70101 Kuopio 10, Finland); Pelkonen, K. *Gen Pharmacol* 10(3): 239-247; 1979.

The tissue-specific responses of drug-metabolizing enzymes to the enzyme inducers phenobarbital (PB) and 3-methylcholanthrene (3-MC) were studied in specific-pathogen-free (SPF) and germfree (GF) male Han-Wistar rats. Rats received 80 mg/kg/day PB ip for 5 days or 100 mg/kg/day 3-MC ip for 3 days; 24 hr after the last dose, they were sacrificed and liver, kidney, and intestinal tissue was analyzed. The activities of NADPH cytochrome c reductase (NCCR), aryl hydrocarbon hydroxylase (AHH), ethoxycoumarin O-deethylase, (ECOD), and uridine diphosphate-glucuronosyl-transferase (UGT) did not differ between SPF and GF rats in any of the tissues examined. Hepatic NCCR activity was slightly enhanced by PB in SPF and GF rats but somewhat decreased by 3-MC in SPF rats. NCCR activity in kidney and intestinal mucosa was unchanged by PB or 3-MC in all rats. AHH activity was not inducible by PB in SPF or GF rats in any tissue examined; 3-MC induced hepatic AHH activity 2.6- to 2.7-fold in both SPF and GF rats, kidney AHH activity 15.2- and 11.7-fold in SPF and GF rats, respectively, and intestinal mucosa AHH activity 5.2- and 6.7-fold in SPF and GF rats. Hepatic ECOD activity was slightly elevated but kidney ECOD activity was unaffected by PB in SPF and GF rats; 3-MC induced hepatic ECOD activity 1.9- and 4-fold (a significant difference) in SPF and GF rats, respectively, and kidney ECOD activity approx 5-fold in both SPF and GF rats. UGT activity was measured both in native and in trypsin-digested microsomes because of the latency of the enzyme. In native hepatic microsomes, UGT was induced slightly by PB but 1.6-fold by 3-MC in both rat groups. In native renal microsomes, only 3-MC caused a significant, although slight, UGT induction in SPF and GF rats. UGT was not inducible in the intestinal postmitochondrial supernatant in SPF or GF rats. In hepatic trypsin-digested microsomes, UGT activity was increased approx 10-fold by PB and 3-MC in SPF and GF rats, compared with the respective native microsomes, but renal trypsin-digested microsomes showed the same UGT activity as native renal microsomes in all cases. Hepatic cytochrome P-450 levels and p-nitroanisole O-demethylase activity were highest in SPF and GF rats following PB administration. (44 refs)

79-5533 Effects of Asbestos and Beryllium on Release of Alveolar Macrophage Enzymes. (Eng) Kang, K. Y. (Dept. Medicine, Tulane Univ. Sch. Medicine, New Orleans, LA); Bice, D.; D'Amato, R.; Ziskind, M.; Salvaggio, J. *Arch Environ Health* 34(3): 133-140; 1979.

The activities of β -N-acetylglucosaminidase, β -glucuronidase, and phosphohexose isomerase increased significantly in the culture medium but not in the mitochondrial fraction of rabbit alveolar macrophages exposed in vitro to asbestos, beryllium sulfate, and beryllium oxide. Asbestos and beryllium sulfate were highly cytotoxic for alveolar macrophages. (21 refs)

79-5534 Chronic Arsenic Poisoning, a Problem in Anesthetic Management. (Eng) Rees, I. (Dept. Anesthesiology, Mount Sinai Sch. Medicine, New York, NY 10029); Adelman, M.; Pratilas, V. *Anesthesiology* 51(1): 84-86; 1979.

A case report illustrating the anesthetic considerations in a 50-yr-old woman with chronic arsenic poisoning from taking daily doses of Fowler's soln for the treatment of psoriasis for 10 yr is presented. A further anesthetic problem in this case was previous tracheal resection for carcinoma due to the arsenism. The patient manifested a generalized neoplastic diathesis of the skin, with cancer formation following nonspecific injuries and numerous

keratoses and granulomatous lesions at the sites of previous injections. (7 refs)

- 79-5535 Changes in Vitamin A Conditioned Hamster Cheek Pouch Epithelium on Exposure to Commercial Shell Lime (Calcium Hydroxide) and Tobacco-II Ultrastructure. (Eng) Kandarkar, S. V. (Cancer Res. Inst., Tata Memorial Centre, Parel, Bombay 400 012, India); Sirsat, S. M. *Indian J Cancer* 15(3): 14-20; 1978.

The effect of lime (commercial shell lime, prepared as a paste) and tobacco (prepared as a plug) on the hamster cheek pouch conditioned by exposure to vitamin A palmitate was studied. Most vitamin A control and all experimental animals showed a roughened cheek pouch mucosa that became more marked with exposure time. The mild hyperplasia seen in the control and solvent (olive oil)-treated tissues was considered normal and subsequent to the trauma of food storage. Epithelial hyperplasia, hyperortho- and parakeratosis, and mild edema occurred after prolonged exposure to vitamin A alone. These changes were enhanced after treatment of the pouches with lime and tobacco, suggesting that longer exposure to these substances might have resulted in malignancy. (30 refs)

- 79-5536 Inducibility of Chromosomal Aberrations by Metal Compounds in Cultured Mammalian Cells. (Eng) Umeda, M. (Tissue Culture Lab., Yokohama City Univ. Sch. Medicine, Urafune-cho, Minami-ku, Yokohama 232, Japan); Nishimura, M. *Mutat Res* 67(3): 221-229; 1979.

Various metal compounds were tested for their ability to induce chromosome aberrations in cultured FM3A cells from a C3H mouse mammary carcinoma. Chromosome aberrations were induced by the application of some Cr, Mn, and Ni compounds. Among the hexavalent Cr compounds, $K_2Cr_2O_7$ and CrO_3 induced high levels of aberrations, at rates that were similar for Cr-equivalent doses. The perchromate compounds were more efficient in producing chromosome aberrations than was a chromate compound, K_2CrO_4 . A trivalent Cr compound, $Cr_2(SO_4)_3$, was less toxic and failed to induce a demonstrable increase in chromosome aberrations. $KMnO_4$ induced aberrations, but at a low rate. As to Ni compounds, $NiCl_2$ and $(CH_3COO)_2Ni$ induced few aberrations. Administration of $K_2Ni(CN)_4$ induced only gaps. NiS induced a low but definite increase in chromosome aberrations. The rate of these aberrations increased with an increase in treatment time from 24 to 48 hr, indicating that there is a time-dependent increase in the hereditary toxicity of metal compounds. $CdCl_2$ and $HgCl_2$ were somewhat toxic, but they failed to induce chromosome aberrations. (23 refs)

- 79-5537 Chromosomal Aberrations and Sister-Chromatid Exchanges in Chinese Hamster Cells Treated In Vitro with Hexavalent Chromium Compounds. (Eng) Majone, F. (Inst. Animal Biology, Univ. Padova, Via Loredan 10, 35100 Padova, Italy); Levis, A. G. *Mutat Res* 67(3): 231-238; 1979.

Chinese hamster ovary (CHO) cells were treated in vitro for 30-39 hr with $K_2Cr_2O_7$ or $Na_2Cr_2O_7$ (0.1 to 1.0 μg of Cr^{6+} /ml) in medium containing bromodeoxyuridine (BUDr). Chromosome aberrations and sister-chromatid exchanges (SCE's) were scored on BUDr-labeled second division metaphases, collected at the end of treat-

ment and stained with Giemsa. Treatment with mitomycin C (0.009-0.030 μg /ml) was carried out as a control for the responsiveness of the cell system to chromosome damage. Both chromium compounds induced marked mitotic delays. Chromosome aberrations were increased about 10-fold by exposure to Cr^{6+} (1.0 μg /ml). The principal aberrations observed were single chromatid gaps, breaks, and interchanges, the frequencies of which increased proportionally with the concentration of chromium. Dicentric chromosomes, isochromatid breaks, and chromosome and chromatid rings were also induced. The frequency of SCE's was scarcely doubled 30 hr after exposure to 0.3 μg /ml Cr^{6+} whereas it was tripled 39 hr after treatment, in the cells whose mitotic cycle had been slowed by chromium. (20 refs)

- 79-5538 Histopathology of Neoplastic and Nonneoplastic Hepatic Lesions in Mice Fed Diets Containing Tetrachlorvinphos. (Eng) Ward, J. M. (Tumor Pathology Branch, Carcinogenesis Testing Program, Room 402, Del Ray Building, Bethesda, MD 20014); Bernal, E.; Buratto, B.; Goodman, D. G.; Strandberg, J. D.; Schueler, R. *J Natl Cancer Inst* 63(1): 111-118; 1979.

A morphological study was made of the hepatocellular carcinomas and unusual nonneoplastic lesions induced in mice by the organophosphorus insecticide tetrachlorvinphos. Tetrachlorvinphos was fed at 8,000 or 16,000 ppm in diets to male and female (C57BL/6N x C3H/HeN)F₁ mice for 80 wk. Surviving mice were killed at 92 wk, and all mice were completely necropsied. In the treated mice, there was a high incidence of unusual nonneoplastic hepatic lesions that were characterized by pericellular fibrosis, hepatocyte nuclear pleomorphism, and intrasinusoidal foci of macrophages with intracytoplasmic crystalline structures. From 84% to 94% of the treated male mice and from 21% to 23% of the treated females had hepatocellular neoplasms. Only 17% of the control males and 7% of the control females had liver tumors. The induced tumors were frequently multiple in the liver, whereas the tumors in the controls were usually singular. The morphology of 241 liver tumors in 110 treated mice was different from that of tumors in controls. Liver tumors in control mice were generally composed of small basophilic hepatocytes. In treated mice, the tumors were hepatocellular carcinomas composed of solid sheets of large basophilic or eosinophilic hepatocytes. Foci of prominent trabecular formation were seen in 51 tumors. Fifteen tumors were composed of small basophilic hepatocytes with oval cells interposed among them. Foci of capillary formation were noted in three of these tumors. In addition, seven more typical hemangiosarcomas in which sinusoids developed and in which thrombosis was frequent were observed. (25 refs)

- 79-5539 Intravesical thio-Tepa. A Study of ³H-Thymidine Uptake in Normal Urothelium and FANFT-induced Tumors in Rats. (Eng) Nieh, P. T. (Urological Service, Massachusetts General Hosp., Boston, MA 02114); Daly, J. J.; Irwin, R. J.; Prout, G. R. *Invest Urol* 16(6): 486-488; 1979.

The effect of the alkylating agent triethylenethiophosphoramide (thio-TEPA: 0.5 ml of a 4 mM soln given transurethrally) on the cell kinetics of normal and neoplastic female Fischer rat urothelium was studied. Half (27) of the weanling rats were pretreated with N-[4-(5-nitro-2-furyl)-2-thiazolyl]formamide (FANFT: 0.188% in the diet for 6 mo), and they all developed gross papillary and sessile bladder tumors by age 9-12 mo. No bladder tumors were found in the 27 animals not exposed to

FANFT. At age 12-14 mo, intravesical instillations of thio-TEPA or saline were performed in all animals. Scintillation counting in both normal and tumorous urothelium exposed to thio-TEPA showed a bimodal pattern, with peaks of DNA synthesis occurring on days 3 and 9 after instillation. Activity in the urothelium of FANFT-treated animals 3 and 9 days after treatment with saline was 40 and 73 counts/min, respectively, compared with 423 ($p < 0.001$) and 437 counts/min ($p < 0.05$) at the same intervals after thio-TEPA treatment. In animals not pretreated with FANFT, counts after saline and thio-TEPA did not differ significantly. Radioautography confirmed these results. Repeat thio-TEPA instillation at 3 and 9 days might improve cytotoxicity and the overall response rate. (8 refs)

79-5540 Sister-Chromatid Exchanges in Human Lymphocytes Exposed During G_0 to Four Classes of DNA-Damaging Chemicals. (Eng) Littlefield, L. G. (Medical and Health Sciences Div., Oak Ridge Associated Univs., P.O. Box 117, Oak Ridge, TN 37830); Colyer, S. P.; Sayer, A. M.; Dufraim, R. J. *Mutat Res* 67(3): 259-269; 1979.

The effectiveness of clastogenic chemicals with different modes of action on DNA in inducing DNA lesions in G_0 lymphocytes that can subsequently be detected as sister-chromatid exchanges (SCE's) was evaluated. Human lymphocytes were treated prior to mitogenic stimulation with varying concentrations of six cytostatic drugs representing four classes of DNA-damaging chemicals. Afterward, the cells were washed to remove residual chemical and cultured in the presence of bromodeoxyuridine (BUdR) for analysis of SCE's. A dose-related increase in SCE's was observed in cells exposed during G_0 to the alkylating chemicals mitomycin C, chlorambucil, and thio-TEPA, but significant increases in SCE's were not noted in cultures exposed to methotrexate, cytarabine, or bleomycin. These findings suggest that not all classes of clastogenic chemicals that induce SCE's in proliferative cells substituted with BUdR are capable of inducing long-lived lesions in the DNA of G_0 lymphocytes that can lead to SCE formation. (40 refs)

79-5541 Platinum(II) Complexes Generate Frame-Shift Mutations in Test Strains of *Salmonella typhimurium*. (Eng) Andersen, K. S. (Inst. Life Sciences and Chemistry, Roskilde Univ., P.O.B. 260, DK 4000 Roskilde, Denmark). *Mutat Res* 67(3): 209-214; 1979.

In the *Salmonella typhimurium* mutagenicity assay, cis-diamminodichloroplatinum(II) (cis-PDD: 2.0 $\mu\text{g}/\text{plate}$) and diaquoethylenediamineplatinum(II) (411 $\mu\text{g}/\text{plate}$) induced histidine revertants in strains TA98 (frameshift mutation) and TA100 (base-pair-substitution mutation). A linear dose-response relationship was found with cis-PDD. *S. typhimurium* strains TA1535, TA1537, and TA1538 were not sensitive to the mutagenic action of cis-PDD. All five strains were sensitive to the toxic effect of cis-PDD. It is concluded that platinum(II) complexes induce mutations (frameshift or base-pair-substitution) only in strains carrying the R-factor plasmid. (12 refs)

79-5542 Mutagenicity, Cytotoxicity and DNA Crosslinking in V79 Chinese Hamster Cells Treated with *cis*- and *trans*-Pt(II) Diamminedichloride. (Eng) Zwelling, L. A. (Lab. Molecular Pharmacology, Div. Cancer Treatment, NCI, NIH,

Bethesda, MD 20014); Bradley, M. O.; Sharkey, N. A.; Anderson, T.; Kohn, K. W. *Mutat Res* 67(3): 271-280; 1979.

The mutagenicity and cytotoxicity of *cis*- and *trans*-platinum(II) diammine dichloride (PDD) were examined in V79 Chinese hamster lung cells, and the results were compared with the effects of these compounds on DNA, as measured by alkaline elution. DNA-protein crosslinks and DNA interstrand crosslinks were detected following doses of *cis*-PDD (10 μM) that reduced cell survival 80%-90% and produced a mutant frequency of 3×10^{-4} at the hypoxanthine-guanine phosphoribosyltransferase locus. Equitoxic doses of *trans*-PDD (320 μM) were much less mutagenic than *cis*-PDD. The *trans*-isomer produced little or no mutagenesis at concentrations up to 600 μM (<1% survival). At equitoxic doses, *trans*-PDD produced more DNA-protein crosslinking than did *cis*-PDD, but interstrand crosslinking for the two isomers was comparable. Hence, the interstrand crosslink could be the cytotoxic lesion produced by these Pt compounds. Neither of these DNA lesions are necessarily mutagenic. The mutagenesis produced by *cis*-PDD could be due to crosslinks of a different type than those produced by *trans*-PDD, or it may be due to monofunctional change. (29 refs)

79-5543 Mutagenic Activity of Sodium Bisulphite in Barley. (Eng) Kak, S. N. (Regional Res. Lab., Jammu Tawi, India); Kaul, B. L. *Experientia* 35(6): 739; 1979.

Hordeum vulgare was used as a test system for the mutagenic activity of sodium bisulfite (7 and 10 mM at 30 C for 6 hr). Both seedling injury and chlorophyll mutations indicated that the compound was highly mutagenic. (9 refs)

79-5544 Cycloheximide Inhibition of Hormonal Induction of α_{2u} -Globulin mRNA. (Eng) Chen, C. L. (Inst. Cancer Res., Coll. Physicians and Surgeons, Columbia Univ., New York, NY 10032); Feigelson, P. *Proc Natl Acad Sci USA* 76(6): 2669-2673; 1979.

Glucocorticoids induce hepatic α_{2u} -globulin (α_{2u} -G) synthesis in isolated hepatocytes by increasing the level of its messenger RNA (mRNA), as measured by cell-free translation and by hybridization to an α_{2u} -G complementary DNA probe. To explore whether the induction of this mRNA is a direct or an indirect consequence of the interaction of the dexamethasone-receptor complex with the α_{2u} -G genome, the requirement for ongoing protein synthesis was examined. A concentration of cycloheximide (0.05 $\mu\text{g}/\text{ml}$) too low to prevent precursor incorporation into total poly(A)-containing RNA prevented the hormonal induction of α_{2u} -G mRNA. Furthermore, incorporation of ^3H -labeled amino acids into total protein was decreased by only 40%-50%, and the appearance of the dexamethasone-induced glycosylated forms of α_{2u} -G was completely prevented in these cycloheximide-treated hepatocytes. The results suggest that the synthesis of a protein mediator(s) may be required for the induction of α_{2u} -G mRNA by glucocorticoids and that the steroid-receptor complex may not interact directly with the α_{2u} -G genome. (27 refs)

79-5545 Acute Toxicity of Methyl Fluorosulfonate (Magic Methyl). (Eng) Hite, M. (Merck Inst. Therapeutic Res., Merck Sharp & Dohme Res. Lab., West Point, PA 19486); Rinehart, W.; Braun, W.; Peck, H. *Am Ind Hyg Assoc J* 40(7): 600-603; 1979.

The po LD₅₀ of methyl fluorosulfonate was estimated to be less than 112 mg/kg in mice. The LC₅₀ for a 1-hr exposure to the vapors of this compound was approximately 0.025-0.029 mg/liter (5-6 ppm) in rats. The compound was severely irritating to the eyes in rabbits and produced toxic signs and death when administered by this route. Methyl fluorosulfonate was also corrosive to the skin and was lethal at a dose of 455-614 mg/kg in rabbits. (5 refs)

79-5546 Carcinogenic N-Nitrosodimethylamine as a Contaminant in Drugs Containing 4-Dimethylamino-2,3-dimethyl-1-phenyl-3-pyrazolin-5-one (Amidopyrine, Aminophenazone). (Eng) Eisenbrand, G. (Deutsches Krebs-Forschungszentrum, Institut für Toxikologie und Chemotherapie, Postfach 10 19 49, Heidelberg, W. Germany); Spiegelhalter, B.; Kann, J.; Klein, R.; Preussmann, R. *Arzneim Forsch* 29(6): 867-869; 1979.

Sixty-eight commercially available drugs containing amidopyrine (AP) were analyzed for possible contamination by the strong carcinogen N-nitrosodimethylamine (NDMA), which can be produced from AP under nitrosating conditions. All drugs contained 1-370 μ g/kg NDMA, 51% containing 1-10 μ g/kg and 40% containing 11-50 μ g/kg. Large variations in NDMA content were found on repeat analyses of the same samples and of pure AP. Exposure of tablets containing 300 mg AP and 160 mg ascorbic acid to 100 ppm NO₂ resulted in increases in NDMA content from 78 μ g/kg to 20,200 μ g/kg within 12 hr. Exposure of similar tablets to 1 ppm NO₂ for 12 hr increased the NDMA content to 5,090 μ g/kg. After 2 and 4 hr exposure to 1 ppm NO₂, the NDMA content increased from 100-180 μ g/kg to 440-510 μ g/kg and 750-800 μ g/kg, respectively. The ascorbic acid content of the tablets did not significantly affect the NDMA content. (9 refs)

79-5547 Demonstration of Effective Antitumor Immunity in an Autochthonous Host Bearing Primary Colon Tumors Induced by 1,2-Dimethylhydrazine Dihydrochloride. (Eng) Bansal, B. R. (Dept. Surgery, Alma Dea Morani Lab. Surgical Immunobiology, Medical Coll. Pennsylvania, 3300 Henry Ave., Philadelphia, PA 19129); Mark, R.; Mobini, J.; Rhoads, J. E.; Bansal, S. C. *J Natl Cancer Inst* 63(1): 127-132; 1979.

The effectiveness of host antitumor immunity induced by the primary tumor against nascent tumors in an autochthonous host was examined in a model rat colon carcinoma induced by 1,2-dimethylhydrazine dihydrochloride (DMH). Inbred WF female rats received DMH sc at a dose of 15 mg/kg/wk in two divided doses from 58 to 112 days of age. Tumors were diagnosed at laparotomy, and sequential laparotomies were done at 30-day intervals. In Group 1 (control), all tumors were left in situ. In Group 2 (control), the first tumor(s) in each rat was isolated from the GI tract (the continuity of which was reestablished) and left in situ for continuous growth in the isolated segment of the colon. In Group 3 (immune), the first tumor(s) in each rat was excised and the continuity of the colon reestablished. In Group 4 (immune), tumors were handled as in Group 3 and the rats received antithymocyte globulin (ATG: 10 mg/kg for 5 days) 7 days after the excision. Excision of the first tumor appeared to induce specific antitumor immune responses, because only 2 additional tumors were observed in the 10 Group 3 rats after excision of the first tumors, whereas 13 and 12 additional tumors were observed in 10 and 9 rats in Groups 1 and 2, respectively, after diagnosis or isolation of the first tumors. Immunosuppression with ATG decreased the effectiveness of the antitumor immunity induced by first tumor exci-

sion, as 7 additional tumors were observed in 10 Group 4 rats. These results suggest that an effective antitumor immunity is induced against successive tumors of an organ after complete excision of a tumor originating in the same organ. The findings are discussed in relation to observations of multiple primary neoplasms in humans. (31 refs)

79-5548 Angiosarcoma of Liver Associated with Phenelzine. (Eng) Daneshmend, T. K. (Bristol Royal Infirmary, Bristol BS2 8HW, England); Scott, G. L.; Bradfield, J. W. *Br Med J* 1(6179): 1679; 1979.

A case of liver angiosarcoma in a woman who had taken phenelzine for at least 6 yr (45 mg/day for the first 3 yr, 15 mg/day thereafter) is reported. There was no history of exposure to thorium dioxide, arsenic, or vinyl chloride. An osteolytic area suggestive of metastatic disease was present in the lateral epicondyle of the right humerus. Phenelzine administration increases the incidence of angiosarcoma in female mice, suggesting a possible etiologic relationship in this patient. (4 refs)

79-5549 Hepatocarcinogenesis by Hydrazine Mycotoxins of Edible Mushrooms. (Eng) Toth, B. (Eppley Inst. Res. Cancer, Univ. Nebraska Medical Center, Omaha, NE). *J Toxicol Environ Health* 5(2/3): 193-202; 1979.

The tumorigenicity of the hydrazine compounds found in two types of edible mushrooms was determined in Swiss mice and Syrian golden hamsters. The wild false morel *Gyromitra esculenta* contains up to 0.3% acetaldehyde methylformylhydrazine and N-methyl-N-formylhydrazine (MFH). The latter chemical, under certain conditions, also yields methylhydrazine. The cultivated mushroom *Agaricus bisporus* contains up to 0.04% β -N-[γ -L-(+)-glutamyl]-4-hydroxymethylphenylhydrazine and 4-hydroxymethylphenylhydrazine (HMPH). MFH (0.0156%-0.001%) was administered in the drinking water of the mice and hamsters continuously, over their life-spans. In both species, the compound induced high incidences of benign and malignant hepatocellular neoplasms. Also, methylhydrazine given in the drinking water (0.01%) induced a significant incidence of malignant histiocytomas in the livers of hamsters. The N'-acetyl derivative of HMPH administered po to mice (0.0625% in the drinking water) gave rise to lung tumors and blood vessel tumors, mainly in the liver. Furthermore, all three compounds produced tumors in various other tissues. Histopathologically, the tumors were classified as benign hepatomas, liver cell carcinomas, angiomas and angiosarcomas of the blood vessels, and adenomas and adenocarcinomas of the lungs. Since mushrooms containing these hydrazine analogs are consumed on a large scale by humans in various parts of the world, their hazardous nature should be considered. (38 refs)

79-5550 Dependence of Tumor Spectrum on Route of Administration in Sprague-Dawley Rats as a Result of Single or Multiple Injections of Methyl(acetoxymethyl)nitrosamine. (Eng) Berman, J. J. (Lab. Experimental Pathology, Div. Cancer Cause and Prevention, NCI, NIH, Bethesda, MD 20205); Rice, J. M.; Wenk, M. L.; Roller, P. P. *J Natl Cancer Inst* 63(1): 93-100; 1979.

The effect of route and schedule of administration of

methyl(acetoxymethyl)nitrosamine (DMN-OAc) to 5-wk-old Sprague-Dawley rats on the tumor spectrum was determined. Sixty females and 361 males were divided into treatment groups of 30 rats; male and female rats received single ip treatments [0.1 millimole (mmol)/kg body wt]; male rats received multiple ip treatments (0.02 or 0.04 mmol/kg x 5), single po or iv treatments (0.1 mmol/kg), or single (0.1 mmol/kg) or multiple (0.02 or 0.04 mmol/kg x 5) sc treatments. The single ip injections induced a high yield of intestinal tract epithelial tumors, particularly in males: 70 tumors were observed in 29 males and 41 tumors in 29 females. Five doses of 0.02 mmol/kg yielded only 51 intestinal tumors in 30 males, but five doses of 0.04 mmol/kg yielded 168 intestinal tumors in 29 males. A significant incidence of nervous system tumors, principally schwannomas arising from small nerves in the serosae of abdominal organs, occurred in rats treated ip with DMN-OAc. Numerous other tumors were found, but not at significant incidences compared with controls. Treatment by routes other than ip virtually eliminated the selectivity of DMN-OAc for the intestines and produced high yields of other tumor types. The single po treatments produced a high yield of stomach tumors (31 and 39 tumors in 2 groups of 30 rats, respectively), mostly adenocarcinomas. The single iv injection yielded 42 lung tumors, 9 Zymbal's gland tumors, and 8 endocardial neurinomas in 31 rats. Single and multiple sc treatments produced a high incidence of mammary tumors 5/30, 7/30, 9/29, soft tissue tumors at the injection site (9/30, 15/30, 15/29), and lung tumors (32/30, 6/30, 32/29, respectively). 79-5551 Metabolism and Activation of 2-Acetylaminofluorene in Isolated Rat Hepatocytes. (Eng) Dybing, E. (Dept. Environmental Toxicology, Natl. Inst. Public Health, Oslo 1, Norway); Soderlund, E.; Haug, L. T.; Thorgeirsson, S. S. *Cancer Res* 39(8): 3268-3275; 1979.

The metabolism of 2-acetylaminofluorene (AAF) and its activation to covalently bound and mutagenic intermediates were studied in isolated male Wistar rat hepatocytes. The cell system readily formed oxidized, deacetylated, and conjugated AAF metabolites. Pretreatment of animals with the inducer β -naphthoflavone led to increases in phenolic and conjugated as well as covalently protein-bound products. Addition of 4-nitrophenol, a substrate for conjugation, increased the levels of free phenols and inhibited the formation of water-soluble metabolites. At the same time, the rates of covalent protein binding were decreased. Formation of 9-hydroxy-2-acetylaminofluorene could also be demonstrated. The pathway leading to this alicyclic hydroxylated AAF metabolite was not induced by prior β -naphthoflavone treatment, nor was it inhibited by 4-nitrophenol addition. The cell system converted AAF as well as 2-aminofluorene and 2,4-diaminoanisole to mutagenic intermediates that were released into the incubation medium. 2-Aminofluorene was considerably more mutagenic than AAF in this system. Addition of microsomes increased the mutagenicity of AAF, but not that of 2-aminofluorene or 2,4-diaminoanisole, presumably by deacetylation of N-hydroxy-2-acetylaminofluorene to N-hydroxy-2-aminofluorene. (52 refs)

79-5552 The Early Effects of Chemical Carcinogens on Adult Rat Hepatocytes in Primary Culture. II. Effects on Unscheduled DNA Synthesis, Cell Division and α -Fetoprotein Production. (Eng) Lowing, R. K. (Health and Safety Executive, Cricklewood, London, England); Fry, J. R.; King, L. J.; Bridges, J. W. *Chem Biol Interact* 25(2/3): 303-319; 1979.

Rat hepatocytes in primary maintenance culture were exposed for 3 hr to a number of carcinogens and noncarcinogens and then studied with respect to cytotoxicity and alterations in mitotic index (MI), unscheduled DNA synthesis (UDS), and α -fetoprotein (AFP) production. The carcinogens tested were 3-methylcholanthrene (3-MC), 2-acetylaminofluorene 2-AAF, 3'-methyl-2-dimethylaminoazobenzene (3'-Me-DAB), and 6-aminochrysene (6-AC), and the noncarcinogens were 2-methyl-DAB and 2-AC. All compounds were cytotoxic at concentrations of 0.1-100 μ M. The carcinogens increased the MI and UDS in cultured hepatocytes, but cytotoxic concentrations of the noncarcinogens did not. 3-MC, 2-AAF, and 6-AC also caused the appearance of AFP in the treated cells, whereas 2-AC did not; AFP was also not detected in untreated cells. The changes in MI, UDS, and AFP production occurred above the background of cytotoxicity. Cytotoxicity, and the increases in MI and UDS were dose-dependent phenomena. The AFP production was transient, commencing approx 24 hr after cessation of exposure and becoming undetectable approx 84 hr after cessation of exposure. The time course of appearance of the increase in MI and AFP production were similar after 3-MC exposure, with the former occurring slightly before the latter, which suggests that AFP production depends on the generation of a cell species functionally distinct from nondividing hepatocytes. The parameters measured in these assays may be useful as part of a screening program for chemical carcinogens. (49 refs)

79-5553 Effects of Piperonyl Butoxide on the Toxicity and Hepatocarcinogenicity of 2-Acetylaminofluorene and 4-Acetylaminobiphenyl, and Their N-Hydroxylated Derivatives, Following Administration to Newborn Mice. (Eng) Fujii, K. (Dept. Pathology, Sch. Medicine, Univ. Tsukuba, Ibaraki, Japan); Epstein, S. S. *Oncology* 36(3): 105-112; 1979.

Studies were conducted to determine whether microsomal enzyme inhibition induced by piperonyl butoxide (PiB) modifies the toxic and carcinogenic effects of 2-acetylaminofluorene (AAF), 4-acetylaminobiphenyl (AAB), and their N-hydroxylated derivatives. Neonatal ICR/Ha mice were injected sc with a single dose of 25, 50, or 100 μ g of AAB, N-hydroxy-4-acetylaminobiphenyl (N-OH-AAB), AAF, or N-hydroxy-2-acetylaminofluorene (N-OH-AAF), alone or together with 2.5% PiB in tricaprillin. Negative control groups were injected with tricaprillin, and positive control groups were injected with 30 μ g of 7,12-dimethylbenz(a)anthracene (DMBA), alone or with PiB. PiB induced synergistic toxicity in the various groups of mice injected with the nonhydroxylated and hydroxylated amine carcinogens or with DMBA, compared with groups injected with carcinogen alone. AAB, N-OH-AAB, AAF, and N-OH-AAF induced dose-related hepatocarcinogenicity in male, but not female, mice, and this effect was not consistently influenced by concomitant administration of PiB. DMBA induced pulmonary adenomas and lymphomas in both sexes and hepatomas in males, and the incidences of these tumors were not modified by PiB. (16 refs)

79-5554 Reactions of the Carcinogen N-Acetoxy-4-acetamidostilbene with Nucleosides. (Eng) Scribner, N. K. (Pacific Northwest Res. Foundation, 1102 Columbia St., Seattle, WA 98104); Scribner, J. D.; Smith, D. L.; Schram, K. H.; McCloskey, J. A. *Chem Biol Interact* 26(1): 27-46; 1979.

Reaction of the carcinogen N-acetoxy-4-acetamidostilbene (N-AcO-AAS) with guanosine, adenosine, or cytidine in aqueous

CHEMICAL CARCINOGENESIS

acetone yielded multiple products. The major product from the reaction with cytidine was a deamination product, 1-(4-acetamidophenyl)-1-(3-uridyl)-2-hydroxy-2-phenylethane. Three minor products were unstable and were characterized only by their UV spectra and pK values. Adenosine yielded two major products, 1-(4-acetamidophenyl)-1-(N⁶-adenosyl)-2-hydroxy-2-phenylethane and 3-(β-D-ribose)-7-phenyl-8-(4-acetamidophenyl)-7,8-dihydroimidazo[2,1-i]purine. The major adduct with guanosine was 1-(4-acetamidophenyl)-1-(1-guanosyl)-2-hydroxy-2-phenylethane. One minor adduct also appeared to be a guanosine-N-1 derivative; two other minor adducts yielded 1-(4-acetamidophenyl)-2-phenyl-1,2-ethanediol on acid hydrolysis and, thus, appeared to be O⁶-derivatives. None of the guanine adducts isolated had the properties of N-7, C-8, or N² adducts. In this respect, N-Aco-AAS appeared to behave more like a classical alkylating agent than like the previously studied N-acetoxy-N-arylacetamides, although the target organs of 4-acetamidostilbene were the same as those of other N-arylacetamides. (34 refs)

- 79-5555 Reactions of the Carcinogen N-Acetoxy-4-acetamidostilbene with Polynucleotides In Vitro. (Eng) Scribner, N. K. (Pacific Northwest Res. Foundation, 1102 Columbia St., Seattle, WA 98104); Scribner, J. D. *Chem Biol Interact* 26(1): 47-55; 1979.

The in vitro reactions of N-Acetoxy-4-acetamidostilbene (N-Aco-AAS) with homopolynucleotides, RNA, and DNA are described. Homopolynucleotides, RNA, and DNA were treated with N-[β-¹⁴C]-Aco-AAS, washed, degraded with S₁ nuclease and acid phosphatase, and chromatographed on Sephadex LH-20. RNA prepared in vitro with ¹⁴C on cytosine, adenine, or guanine was treated with nonradioactive N-Aco-AAS and then digested and chromatographed similarly. By this means, many of the adducts arising from nucleoside reactions were shown to result from the treatment of nucleic acids with the same carcinogen; in addition, several products that have not been matched to products of monomer alkylation also resulted. Labeled 1-(4-acetamidophenyl)-2-phenyl-1,2-ethanediol was detected in the digest of RNA treated with radioactive N-Aco-AAS, which suggests that phosphate alkylation had taken place. (13 refs)

- 79-5556 Microsomal Metabolism of Arylamides by the Rat and Guinea Pig - II. Oxidation of 3-Fluorenyl acetamide at Carbon Atom 9 Formation of 3-Acetamido-9-Fluorenone. (Eng) Kaplan, E. (Lab. Cancer Res., Veterans Admin. Hosp., Minneapolis, MN 55417); Gutmann, H. R. *Biochem Pharmacol* 28(10): 1609-1614; 1979.

The formation of 9-hydroxy-3-fluorenylacetamide (9-hydroxy-3-FAA) from N-3-fluorenylacetamide (3-FAA) was examined in order to ascertain whether the formation of the ketone 3-acetamido-9-fluorenone (9-oxo-3-FAA8) is catalyzed by the same enzyme(s). In addition, the intracellular distribution of the microsomal enzyme(s) involved in the formation of 9-oxo-3-FAA and of 9-hydroxy-3-FAA was investigated. Two pathways are theoretically possible for the formation of 9-oxo-3-FAA from 3-FAA: it could arise from 3-FAA by way of the intermediate, 9-hydroxy-3-FAA, or the arylamide could yield the ketone by an oxidative mechanism at Carbon 9 (C-9) not involving the intermediate formation of the alcohol. Data is presented which demonstrates that although both reactions are oxidative, the marked differences in the cofactor requirements for hydroxylation of 3-FAA and for oxidation of 9-hydroxy-3-FAA indicated that the two

reactions are catalyzed by different enzymes. It was previously shown that CO inhibits the hydroxylation of 3-FAA at C-9 by 70%-80%. No inhibitory effect of CO was observed on the dehydrogenation of 9-hydroxy-3-FAA to 9-oxo-3-FAA. This, plus results of studies concerning pH changes, led to the conclusion that the subsequent oxidation of the alcohol to the ketone is not catalyzed by a microsomal heme protein and that the two oxidative reactions are attributable to two separate enzymes. Final evidence for two distinct enzymes came from the determination of the intracellular distribution of the hydroxylating and of the dehydrogenating activities. While 85%-90% of the hydroxylating activity was concentrated in the microsomal fraction, the dehydrogenating activity was approx equally distributed between the microsomal and the soluble fractions. The ketone-forming enzyme utilized NADP⁺ and NAD⁺ and did not appear to be a heme protein, in contrast to the alcohol-forming enzyme. (15 refs)

- 79-5557 Nitrous Acid Mutagenesis of Duplex DNA as a Three-Component System. (Eng) Thomas, H. F. (Dept. Medical Genetics, Univ. Wisconsin, Madison, WI 53706); Hartman, P. E.; Mudryj, M.; Brown, D. L. *Mutat Res* 61(2): 129-151; 1979.

The effect of nitrosation of a variety of compounds on the mutagenesis of duplex DNA by nitrous acid (NA) was studied. Denatured DNA from *Hemophilus influenzae* was readily mutated by NA to give kanamycin-resistant (KR) and erythromycin-resistant (ER) mutants. The low linear rate of induction of ER mutants with NA alone was increased when putrescine or phenol was present in the reaction mixture. There was a requirement for continuous generation of nitrosophenol for optimal mutagenesis. Using KR as a selective marker, NA was mutagenic for native DNA only when one of the four common polyamines was added to the reaction mixture. The method of DNA preparation was important in ensuring freedom from low-mol-wt molecules capable of enhancing NA mutagenesis of native DNA. Appreciable stimulation of the production of KR mutants occurred when 0.02-0.2 mM spermine was present in the reaction mixture, and, at a standard spermine concentration, the rate of mutation induction to KR increased with increasing concentrations of NaNO₂. The rate of NA mutagenesis in the presence of spermine was also a function of pH (optimum, 4.5-4.6). A variety of diamines, alcohols, and glycols was able to promote NA mutagenesis. The half-life of the spermine reaction product was about 4 min. NA reaction mixtures containing spermine or ethanol possessed greater mutagenic activity for *Salmonella typhimurium* than did NA alone. Spermine specifically enhanced the reversion of a base-substitution mutation and had no stimulatory effect on the reversion of frameshift mutations. All three *Escherichia coli* loci were susceptible to NA mutagenesis, but the addition of polyamine enhanced only the frequency of base-substitution mutations. (92 refs)

- 79-5558 Inhibition of N-n-Butyl-N-(4-hydroxybutyl) nitrosamine-induced Urinary Bladder Cancer in Rats by Administration of Disulfiram in the Diet. (Eng) Irving, C. C. (Veterans Admin. Medical Center, 1030 Jefferson Ave., Memphis, TN 38104); Tice, A. J.; Murphy, W. M. *Cancer Res* 39(8): 3040-3043; 1979.

The effect of disulfiram (Ds) on the induction of urinary bladder cancer in rats given N-n-butyl-N-(4-hydroxybutyl) nitrosamine (BHN) was examined. Adult male Wistar rats were divided into four groups: (1) control diet, 30 rats; (2) control diet plus 0.025%

BHBN in the drinking water, 60 rats; (3) control diet containing 0.5% DS, 30 rats; and (4) control diet containing 0.5% DS plus 0.025% BHBN in the drinking water, 60 rats. The animals were kept on these regimens for 15 wk and then were transferred to and maintained on the control diet. The av total intake of BHBN was 1.21 g/rat for Group 2 and 1.23 g/rat for Group 4. The cumulative incidences of bladder cancer at 25 wk after initial exposure to BHBN were: Group 1, 0/9; Group 2, 27/27; Group 3, 0/9; and Group 4, 0/27. At the end of the experiment (32-42 wk), the final bladder cancer incidences were: Group 1, 0/30; Group 2, 57/57; Group 3, 0/24; and Group 4, 7/55. Except for a carcinoma of the renal pelvis in one rat in Group 2 and the bladder tumors in Groups 2 and 4, tumors were not detected in other organs of any of these rats. It was concluded that DS significantly inhibited the induction of bladder cancer in rats exposed to BHBN. The mechanism of action of DS in this process is being investigated. (24 refs)

79-5559 Dose-dependent DNA Ruptures Induced by the Procarcinogen Dimethylnitrosamine on Primary Rat Liver Cultures. (Eng) Mendoza-Figueroa, T. (Departamento de Biología Celular, Centro de Investigación y de Estudios Avanzados del IPN, Ap. Postal 14-740 Mexico City 14, Mexico); Lopez-Revilla, R.; Villa-Trevino, S. *Cancer Res* 39(8): 3254-3257; 1979.

The amount of breakage produced by dimethylnitrosamine (DMN) in the DNA of primary male Wistar rat liver cultures was measured. Rat liver cells were isolated 20-24 hr after partial hepatectomy, cultured, and pulse-labeled in vitro with [³H]thymidine. Radioactively labeled cultures were treated with DMN or with the direct carcinogen N-methyl-N'-nitro-N-nitrosoguanidine (MNNG) and then lysed directly onto alkaline sucrose gradients. DMN and MNNG caused a dose-dependent reduction in the mol wt of the DNA, and MNNG was approx 1,000 times more potent than DMN. DNA breaks appeared to be carcinogen-specific and not due to cell death, since treatment with high doses of cycloheximide, a noncarcinogenic hepatotoxic agent, was without significant effect. The data indicate that detection of DNA breaks constitutes a more sensitive assay of DMN effects than determination of unscheduled DNA synthesis in primary liver cultures. Quantitation of DNA breaks in liver cells may have value as a short-term assay for the identification of possible carcinogens and procarcinogens. (22 refs)

79-5560 Importance of Hepatic Neoplasms in Lower Vertebrate Animals as a Tool in Cancer Research. (Eng) Ishikawa, T. (Dept. Experimental Pathology, Cancer Inst., Tokyo, Japan); Takayama, S. *J Toxicol Environ Health* 5(2/3): 537-550; 1979.

The histological and autoradiographic findings are reported on hepatic tumors induced in medakas (*Oryzias latipes*) by the addition of diethylnitrosamine (DEN) to their aquarium water, and the effect of the length of carcinogen exposure on tumor incidence is discussed. The tanks were kept in incubators at temperatures of 25 C or 18 C. At 25 C, water-soluble DEN was added to the water at concentrations of 15, 30 or 45 ppm for 8 wk. At 18 C, a single dose of DEN (45 ppm) was added for 8 wk, after which the fish were maintained in normal water at 18 C for 6 more wk. Fish were selected randomly from each group at weekly or biweekly intervals and studied using light microscopy. Autoradiographic studies were conducted on 5 fish in the group treated with 30 ppm DEN weekly throughout the 8-wk experimental period. To investigate the effect

of DEN exposure period on the incidence of liver tumors, ten tanks of fish were exposed to a single dose of DEN (45 ppm) for 3 days or 1, 2, 4, or 6 wk at 25 C, after which time the fish were maintained in normal water. At the end of 13 wk, the survivors were killed and their liver tumor incidence determined. Liver tumors appeared as early as 5 wk after the beginning of treatment with DEN, and most of the fish treated with high concentrations had tumors by 6-8 wk. Multiple bizarre, basophilic cell foci arose among degenerating parenchymal cells after 4-5 wk treatment with DEN. The bizarre cells appeared to be resistant to the toxicity of DEN and were shown to be highly proliferative by autoradiography. Tumor incidence increased in proportion to the exposure period, and exposure to 45 ppm DEN for 2 wk was required for tumor development at 13 wk. At lower temperatures, the tumors were found in 1/3 fish at 8 wk; and the tumors were smaller than those observed at 25 C, even after 12-14 wk treatment. The use of these fish in carcinogenic studies is discussed. (30 refs)

79-5561 Changes in the Labeling Index and DNA Content of Liver Cells During Diethylnitrosamine-induced Liver Tumorigenesis in *Oryzias latipes*. (Eng) Kyono, Y. (Zoological Inst., Faculty Science, Univ. Tokyo, Bunkyo-ku, Tokyo 113, Japan); Shima, A.; Egami, N. *J Natl Cancer Inst* 63(1): 71-74; 1979.

Changes in DNA synthesis and DNA levels in liver cells during diethylnitrosamine (DENA)-induced hepatocarcinogenesis in medaka fish (*Oryzias latipes*) were measured by autoradiography and Feulgen-DNA cytofluorometry. The fish were kept for 6 wk in water containing DENA (100 ppm). A single pulse of 1 μ Ci ³H-thymidine was given ip to each fish 2 hr before sacrifice, and the labeling indices of five to seven fish were counted throughout the 13 wk of the experiment. After 1 wk, the indices in both parenchymal and nonparenchymal cells were at control levels, but they increased rapidly at 2 wk and stayed high during DENA treatment. However, the indices decreased immediately after the fish were transferred into water without DENA. Tumor nodules of various sizes were observed at 11-13 wk. The labeling index in the basophilic hyperbasophilic cells in these nodules was increased, but the indices in the parenchymal and nonparenchymal cells fell to control levels at 11-13 wk. Parallel with histologic studies, the nuclear DNA level of each hepatocyte was measured by Feulgen-DNA cytofluorometry and autoradiography. DNA levels, became widely distributed even before appreciable histologic changes could be detected. During treatment of the fish with DENA, DNA levels in the labeled hepatocytes ranged from the normal diploid of 2C to >6C. When the tumor nodules were studied histologically, the DNA distribution histogram was found to be similar to that of controls except for the presence of hepatocytes with higher DNA levels (around 6C). (16 refs)

79-5562 Effect of Diethylnitrosamine on the Rat Liver Protein-synthesizing System. (Rus) Osipova, L. A. (Dept. Simulation Tumor Process, Inst. Oncological Problems, Kiev, USSR); Grinchishin, V. P. *Vopr Onkol* 25(6): 54-59; 1979.

The effect of a single dose of diethylnitrosamine (DENA) on rat liver protein synthesis was evaluated in random-bred albino rats. Animals were subjected to partial hepatectomy and, 24 hr later, inoculated ip with DENA (0.05% soln, 1 ml/100 g). The rats were sacrificed at various times after surgery, and the level of free and membrane-bound polyribosomes, as well as the rate of incorporation of messenger RNA (mRNA) into both types of

polyribosomes, were determined. The single injection of DENA caused a significant decrease in the amount of membrane-bound polyribosomes on days 4-5 and 21-28 after hepatectomy. DENA also inhibited the hepatectomy-induced increase of mRNA incorporation into both free and membrane-bound polyribosomes. (13 refs)

- 79-5563 Prolonged Induction of Hepatic Ornithine Decarboxylase and Its Relation to Cyclic Adenosine 3':5'-Monophosphate-dependent Protein Kinase Activation after a Single Administration of Diethylnitrosamine. (Eng) Olson, J. W. (Dept. Pharmacology, Coll. Medicine, Univ. Arizona Health Sciences Center, Tucson, AZ 85724); Russell, D. H. *Cancer Res* 39(8): 3074-3079; 1979.

The effects of a single carcinogenic dose of diethylnitrosamine (DEN: 200 mg/kg ip) on the time and extent of ornithine decarboxylase (ODC) induction and cyclic AMP (cAMP)-dependent protein kinase (PK) activation were investigated in male Sprague-Dawley rats. After a single injection of DEN, there was a rapid increase in the activity ratio of hepatic cAMP-dependent PK activity (within 1 hr) followed by the induction of ODC activity, which was detectable by 3 hr. Both the cAMP-dependent PK activity ratio and ODC activity were significantly elevated above control levels for 7 days following DEN administration. A single non-carcinogenic dose of DEN (25 mg/kg) did not increase the cAMP-dependent PK activity ratio or induce ODC activity at 24 hr postadministration. However, serial administration of DEN (25 mg/kg) for 4 or 7 days resulted in an increased cAMP-dependent PK activity ratio and increased ODC activity. This is the first report of a prolonged increase in both the activity ratio of hepatic cAMP-dependent PK and the activity of ODC in response to a single carcinogenic dose of DEN. (50 refs)

- 79-5564 Carcinogenicity of N-Nitrosobis(2-hydroxypropyl)amine and N-Nitrosobis(2-oxopropyl)amine in MRC Rats. (Eng) Pour, P. (Eppley Inst. Res. Cancer, Univ. Nebraska Medical Center, 42d St. and Dewey Ave., Omaha, NE 68105); Salmasi, S.; Runge, R.; Gingell, R.; Wallcave, L.; Nagel, D.; Stepan, K. *J Natl Cancer Inst* 63(1): 181-190; 1979.

To further elucidate the relationship between the molecular structures of carcinogens and their target tissues in various species and strains, the effects of N-nitrosobis(2-hydroxypropyl)amine (BHP) and N-nitrosobis(2-oxopropyl)amine (BOP) were tested in Wistar-derived MRC rats. Weekly sc injections of equitoxic doses of BHP and BOP (1/10, 1/20, or 1/40 of the LD₅₀) to the rats induced tumors at various sites. The incidence, latency, multiplicity, morphologic type, and distribution of these tumors varied according to the compound given. The esophagus was the main target organ for BHP (100%), followed by the respiratory tract (87%), pharynx (80%), colon and liver (each 73%), kidneys (20%), thyroid gland (20%), and urinary bladder and urethra (each 7%). BOP was ineffective in the esophagus and pharynx, but it induced a higher incidence of tumors in the kidneys (27%), thyroid gland (60%), urinary bladder (33%), and urethra (73%) and fewer neoplasms in the respiratory tract (20%), colon (67%), and liver (53%). In addition, BOP caused a few, apparently primary, prostate squamous cell carcinomas. When results were compared with those of BHP treatment in Sprague-Dawley rats and BHP and BOP treatment in Syrian golden hamsters, there were remarkable species and/or stock differences in the carcinogenic response. The reasons for these differences remain speculative. (34 refs)

- 79-5565 DNA Repair Synthesis in Mice Spermatids after Treatment with N-Methyl-N-nitroso-urea and N-N-Dimethylnitrosamine: Preliminary Results. (Eng) Cesarone, C. F. (Inst. Oncology, Sch. Medicine, Univ. Genoa, V.le Benedetto XV, 10 Pad. B., 16132 Genoa, Italy); Bolognesi, C.; Santi, L. *Toxicology* 12(2): 183-186; 1979.

Two methylating agents, N-methyl-N-nitrosourea (MNU: 50 or 75 mg/kg, ip) and N,N-dimethylnitrosamine (DMN: 2 or 4 mg/kg, ip), were used to evaluate a new short-term test of DNA repair synthesis based on the unscheduled incorporation of tritiated thymidine (TdR) into spermatogenic cells of male C3H mice. In the germ cells obtained from animals treated with MNU, an unscheduled DNA synthesis could be detected on the 10th day after treatment. On the 12th day, a direct dose-response relationship could be observed, and the effect persisted until the 18th day. In the animals treated with DMN, a variation in TdR incorporation was detected on day 16 after injection of the drug. The repair synthesis induced in mouse germ cells could be conveniently detected by liquid scintillation counting. (18 refs)

- 79-5566 Selected Morphological Immunocytochemical and Growth Characteristics of Three Experimental Rat Gliomas and of Their Cells In Vitro. (Eng) Stavrou, D. (Lehrstuhl für Allgemeine Pathologie und Neuropathologie, Institut für Tierpathologie der Universität München, Veterinarstrasse 13, D-8000 Munich 22, W. Germany); Osterkamp, U.; Schroder, B.; Anzil, A. P.; Zanker, K. *Exp Cell Biol* 47(1): 3-21; 1979.

Morphological and immunocytochemical studies were made of experimental brain tumors chemically induced in rats and of the cell lines established from them. Nervous system tumors were induced in Sprague-Dawley and Long-Evans rats by weekly administrations of 6 mg/kg N-methyl-N-nitrosourea in the drinking water. Three of these tumors, a grade 2 mixed glioma, a grade 2-3 astrocytoma, and a grade 1-2 oligodendroglioma, were established in culture and propagated in vitro. The mixed glioma line (75SD-G-376) and the astrocytoma line (75SD-G-420) were repeatedly subcultured, cloned at passages 90 and 120, and designated as clones 75SD-G-376C and 75SD-G-420C, respectively. The growth rate of the oligodendroglioma cell strain (77LE-G-180) was very low, and the cells died off after the fifth in vitro passage. The glial nature of all the lines was ascertained by demonstrating the presence of S-100 protein in the culture cells. Approx 2.5 yr after the 75SD-G-376 and 75SD-G-420 primary cultures were established, mass cultures as well as clones derived from them were still producing S-100 and, thus, were clearly comparable to the primary cultures, at least in this respect. However, light microscope studies showed that cells of the clonal lines, which had processes that grew shorter and became less abundant with increasing passage level, differed morphologically from cells of the primary cultures and their uncloned lines. Therefore, the cell morphology of these clones can be viewed as a form of adaptation to in vitro conditions. It is concluded that permanent cell lines with well-defined properties can be grown from experimental brain gliomas successfully established in culture and maintained in vitro. (32 refs)

- 79-5567 The Stability of Methylated Purines and of Methylphosphotriesters in the DNA of V79 Cells after Treatment with N-Methyl-N-Nitrosourea. (Eng) Warren, W. (Inst. Cancer Res., Royal Cancer Hosp., Pollards Wood Res. Station, Nightingales Lane, Chalfont St. Giles, Bucks HP8 4SP, England); Crathorn, A.R.; Shooter, K.V. *Biochim Biophys Acta* 563(1): 82-88; 1979.

V79-379A cells growing in suspension culture were treated with N-methyl-N-nitrosourea at concentrations of 0.6 and 1.2 mM. After incubation for periods from 1 to 48 hr, DNA was isolated from the cells and the concentrations of 7-methylguanine, O⁶-methylguanine, 3-methyladenine, and methyl phosphotriesters were determined. After correction for dilution resulting from DNA synthesis during the incubation, it was found that no loss of O⁶-methylguanine or methyl phosphotriesters occurred; 7-methylguanine disappeared with a half-life of 22 hr, and 3-methyladenine was detectable only immediately after the initial treatment. The results show that these cells eliminate 7-methylguanine and 3-methyladenine from DNA by a repair process but are unable to excise or repair O⁶-methylguanine or methyl phosphotriesters. (28 refs)

79-5568 Influence of Hydrogen Bonding in DNA and Polynucleotides on Reaction of Nitrogens and Oxygens Toward Ethylnitrosourea. (Eng) Bodell, W. J. (Lab. Radiobiology, Univ. California, San Francisco, CA 94143); Singer, B. *Biochemistry* 18(13): 2860-2863; 1979.

An attempt was made to determine whether the reactivity of base-paired nitrogens and oxygens is influenced by the transient opening of the DNA helix as a function of temperature. The reactivity of ethylnitrosourea toward hydrogen-bonded sites in double-stranded DNA or poly(rA)-poly(rU) was compared with the reactivity toward those sites in single-stranded DNA, RNA, or poly(rA). Alkylation of the N-1 of adenine in poly(rA)-poly(rU) was almost suppressed at 5 C but could be markedly increased by raising the reaction temperature to 25 C, well below the T_m of 56 C. In contrast, the N-7 and N-6 of adenine, which are not hydrogen-bonded, reacted to the same extent at temperatures ranging from 5 to 65 C. The extent of reaction at the N-3 of adenine varied inversely with the reactivity of the N-1 of adenine, indicating that of these two nitrogens, N-1 is the most reactive. The proportion of reaction at the various nitrogens in poly(rA) was not affected by temperature. The hydrogen-bonded oxygens in double-stranded DNA are the O-6 of guanine, the O-4 of thymine, and the O-2 of cytosine. All are equally reactive at 5, 25, and 51 C. It is concluded that the observed temperature independence is due to these oxygens having an electron pair not involved in hydrogen bonding and, thus, available for reaction. In contrast, the electron pair of the N-1 of adenine (or the N-3 of cytosine) is involved in hydrogen bonding, and the extent of their reactivity is dependent on thermal fluctuation providing transiently open base pairs at temperatures far below the T_m. (22 refs)

79-5569 Transmission Electron Microscopy of Fetal Rat Brain Cells During Neoplastic Transformation in Cell Culture. (Eng) Haugen, A. (Human Tissue Studies Section, Lab. Experimental Pathology, Div. Cancer Cause and Prevention, NCI, NIH, Bethesda, MD 20205); Laerum, O. D. *J Natl Cancer Inst* 63(2): 455-464; 1979.

Fetal rat brain cells were investigated by transmission electron microscopy during neoplastic transformation in long-term cell cultures to determine if the cells gradually acquire surface alterations characteristic of malignant cells. Before transfer of the cells to culture, BD-IX rat fetuses were treated with a single transplacental pulse of N-ethyl-N-nitrosourea (75 µg/g) on gestation day 18. During the early stages (3-4 mo), both gliallike and neuronlike cells were present in the culture, and after 2 mo they formed complex aggregates (nodules). In contrast, corresponding

secondary control cultures consisted of flat, epithelioid neural cells without neuron or astrocyte differentiation. After 3 mo, cells with a neuron morphology gradually disappeared. Some of the remaining cells contained many autophagosomes. After 5 mo, the rapid proliferation of rather homogeneous, gliallike populations was accompanied by a reduction in the number of microfilament bundles, microtubules, and atypical nuclei. The ability of the cells to form tumors upon sc implantation into syngeneic hosts was not observed until about 3 mo later. (27 refs)

79-5570 Effect of n-Ethylnitrosourea on Rat Embryos. (Rus) Aleksandrov, V. A. (Lab. Experimental Tumors, N. N. Petrov Res. Inst. Oncology, Leningrad, USSR). *Vopr Onkol* 25(6): 60-65; 1979.

The embryotoxicity and transplacental carcinogenicity of N-ethylnitrosourea (ENU) was studied in random-bred rats. Pregnant rats received a single iv injection of 20, 30, or 80 mg/kg ENU between days 1 and 22 of pregnancy. Administration of 20 mg/kg ENU on days 1 and 3-9 resulted in significant embryonal lethality. The teratogenic effect of ENU was most pronounced after administration on days 9 and 10. A significant increase in the incidence of tumors in the offspring was recorded after administration of ENU on day 11 (48.3% vs 9.7% in the offspring of rats inoculated with 20 mg/kg on days 8, 9, or 10). The incidence of tumors showed a progressive increase from 60.4% after inoculation on day 12 to 95.2% after inoculation on day 22. Most of the ENU-induced tumors were located in the CNS; more than one-half of neurogenic tumors were located in the brain. (8 refs)

79-5571 Carcinogenicity of Chlorinated Nitrosotrialkylureas in Rats. (Eng) Lijinsky, W. (Chemical Carcinogenesis Program, Frederick Cancer Res. Center, Frederick, MD 21701); Taylor, H. W. *J Cancer Res Clin Oncol* 94(2): 131-137; 1979.

Four chlorinated nitrosotrialkylureas, which have been introduced for the treatment of cancer, were tested for carcinogenicity following po administration to Sprague-Dawley rats. The chemicals were mixed in oil at concentrations of 1.1-21.5 mg/ml, and 0.2 ml of this soln was given twice weekly for 1-50 wk. Among 45 males given nitrosochloroethylidimethylurea, 10 developed papillomas of the forestomach, 2 developed carcinomas of the forestomach, 2 developed papillomas of the esophagus, and 11 developed alveolar cell adenomas in the lung; there were 23 tumors at other sites. Among 15 males given nitrosochloroethylidimethylurea, 2 developed papillomas of the forestomach, 1 developed an alveolar adenoma, and 2 developed squamous cell carcinomas of the lung; there were 7 tumors at other sites. Of 30 females given nitrosomethylbis(chloroethyl) urea, 3 developed papillomas of the forestomach, 3 developed carcinomas of the forestomach, 1 developed a papilloma of the esophagus, and 1 developed a squamous cell carcinoma of the lung; there were 11 tumors at other sites. Of 30 females given nitrosotris(chloroethyl)urea, 9 developed papillomas of the forestomach and 2 developed alveolar cell adenomas; there were 13 tumors at other sites. (4 refs)

79-5572 Induction of Hepatic Tumors in Rats by Senkirkine and Symphytine. (Eng) Hirono, I. (Dept. Carcinogenesis and Cancer Susceptibility, Inst. Medical Science, Univ. Tokyo, Shirokanedai 4-6-1, Minato-ku, Tokyo 108, Japan);

Haga, M.; Fujii, M.; Matsuura, S.; Matsubara, N.; Nakayama, M.; Furuya, T.; Hikichi, M.; Takanashi, H.; Uchida, E.; Hosaka, S.; Ueno, I. *J Natl Cancer Inst* 63(2): 469-472; 1979.

The carcinogenicity of the pyrrolizidine alkaloids senkirkine and symphytine, which are found in coltsfoot and comfrey plants, was studied in male inbred ACI rats. Animals were divided into three groups: Groups 1 and 2 received ip injections of freshly prepared senkirkine and symphytine, respectively, at a dose of 10% of the LD₅₀ 2x/wk for 4 wk and then 1x/wk for 52 wk. Group 3 (control) was given ip injections of a 0.9% NaCl soln by the same injection schedule. All Group 1 rats survived for >290 days after the start of the injections, and 9/20 rats developed liver cell adenomas. All Group 2 animals survived for >330 days after the start of injections. Of 20 rats, 4 had liver tumors, 3 had hemangioendothelial sarcomas, and 1 had a liver cell adenoma. The hemangioendothelial sarcomas metastasized to the lungs of two rats. The control group had no liver tumors. (13 refs)

79-5573 Sister-Chromatid Exchanges and Chromosomal Breakage in Patients Treated with Cytostatics. (Eng) Musilova, J. (3rd Medical Dept., Charles Univ., Prague, Czechoslovakia); Michalova, K.; Urban, J. *Mutat Res* 67(3): 289-294; 1979.

The frequency of structural chromosome rearrangements and sister-chromatid exchanges (SCE's) in six patients being treated with cytostatic drugs was investigated in short-term phytohemagglutinin-stimulated lymphocyte cultures by means of bromodeoxyuridine substitution and the fluorescence plus Giemsa (FPG) staining technique. Both parameters were significantly increased in patients treated with comparatively low doses of cyclophosphamide, busulfan, and adriamycin. The increased SCE rate was proportional to the number of chromosome breaks, with the ratio of SCE's to breaks being about 100:1. The SCE number remained high for several months after the termination of cytostatic therapy, when the conventional analysis of chromosome breaks yielded normal results. Normal SCE values were obtained in two patients treated with low doses of fluorouracil. (11 refs)

79-5574 The Mutagenic Activity of Anti-Cancer Drugs and the Urine of Rats Given These Drugs. (Eng) Pak, K. (Dept. Urology, Faculty Medicine, Kyoto Univ., Sakyo-ku, Kyoto, Japan); Iwasaki, T.; Miyakawa, M.; Yoshida, O. *Urol Res* 7(2): 119-124; 1979.

The ability of 21 anticancer drugs to induce mutations in *Salmonella typhimurium* tester strains was determined in the Salmonella/microsome mutagenicity assay. Nine of the 21 anticancer drugs were mutagenic: cyclophosphamide, nitroimin, thio-TEPA, busulfan, 6-mercaptopurine, neocarzinostatin, daunomycin, adriamycin, and estramustine phosphate. Seven of these mutagens were injected continuously into the jugular veins of female Wistar rats. Urine was collected through a cystostomy tube and tested for mutagenicity. The urine from rats treated with 6/7 drugs (cyclophosphamide, nitroimin, thio-TEPA, neocarzinostatin, adriamycin, and daunomycin) was mutagenic. (23 refs)

79-5575 An Evaluation of the Use of Peripheral Blood Lymphocyte Systems for Assessing Cytological Effects In-

duced In Vivo by Chemical Mutagens. (Eng) Natarajan, A. T. (Dept. Radiation Genetics and Chemical Mutagenesis, Sylvius Lab., Univ. Leiden, Post Bus 722, Leiden, Netherlands); van Buul, P. P.; Raposa, T. In: *Mutagen-induced Chromosome Damage in Man. Proceedings of a Symposium held in Edinburgh, Scotland, July 7-8, 1977*. Medical Research Council (Edinburgh, Scotland): 355 pp.; 268-274; 1978.

The use of peripheral blood lymphocyte systems for monitoring populations exposed to chemical mutagens and for screening chemicals for their in vivo mutagenic effects was investigated. Investigations included analyses of the frequency of chromosome aberrations in workers exposed to low levels of vinyl chloride; the frequencies of sister chromatid exchanges (SCE's) in blood lymphocytes from patients receiving cytostatic treatment, both during treatment and a few weeks after recovery; and chromosome aberrations and SCE's in lymphocytes of rats after in vivo treatment with directly and indirectly acting alkylating agents. No strongly significant difference was noted between the control and vinyl chloride groups of workers with regard to the occurrence and frequency of chromosome aberrations. Of the six patients treated with cytostatic drugs, five received cyclophosphamide and one thiopeta. The control group had an av of 10.3 SCE's/cell, while in the treated group two patients had significantly higher frequencies of SCE's. In a 76-yr-old patient with reticular cell sarcoma, the SCE frequencies were 23.4, 15.6, 16.2, and 12.3 per cell on days 13, 16, 18, and 20 of therapy, while the frequency decreased to 6.3 25 days after therapy was terminated. In rats, despite a very high dose of diethylnitrosamine (DEN), no effect on SCE's and chromosomal aberrations could be observed. With both dimethylnitrosamine and methyl nitrosourea, a dose-dependent increase in chromosome aberrations and SCE's was found. It is concluded that for low chronic exposures, this system is not sensitive in detecting mutagenic effects, while for assessing the in vivo effects of chemical mutagens, particularly those that need metabolic activation, this system may have value. (10 refs)

79-5576 Isolation of a Recombination Deficient *Agrobacterium tumefaciens* Mutant. (Eng) Klapwijk, P. M. (Dept. Biochemistry, State Univ. Leiden, P.O. Box 9505, 2300 RA Leiden, Netherlands); van Beelen, P.; Schilperoort, R. A. *Mol Gen Genet* 173(2): 171-175; 1979.

The isolation of a recombination deficient (Rec⁻) strain of *Agrobacterium tumefaciens* is described. Strain LBA 4011 was mutagenized with nitrosoguanidine, and after segregation 18,000 colonies were replica plated and UV irradiated. Twenty-two UV-sensitive strains were isolated and tested for methylmethanesulfonate (MMS) sensitivity. Six of these strains were more MMS-sensitive than LBA 4011. A Ti plasmid that was genetically marked with Tn 1 [Cb(R)] was introduced in these strains, and the rescue of the Cb(R) marker during superinfection with an incompatible cointegrate plasmid Ti::R 702 was determined. One strain exhibited a large reduction in rescue frequency. It is concluded that the latter strain was recombination deficient. This property did not influence the induction of plant tumors. (21 refs)

79-5577 Differential DNA Damage Induced by Chemical Mutagens in Cells Growing in a Modified Selye's Granuloma Pouch. (Eng) Lee, I. P. (Natl. Inst. Environmental Health Sciences, NIH, Research Triangle Park, NC); Zbinden, G. *Exp Cell Biol* 47(2): 92-106; 1979.

Interactions of carcinogens with the DNA of rapidly growing granulation tissue were studied in a modified Selye's granuloma pouch in male albino rats (strain ZUR:SIV-Z). Rapid growth of granulation tissue was induced in the rats by the injection of 0.25% croton oil into an sc air pocket. The growth characteristics of the granulation tissue were evaluated by histopathologic techniques and by measuring ^3H -thymidine incorporation into DNA. The DNA of the granuloma cells was labeled with ^3H -thymidine. Subsequently, four classes of test chemicals (monofunctional and polyfunctional alkylating agents, DNA intercalating agents, and chemicals not known to interact with DNA) were injected ip. The presence of single-stranded breaks was assayed in granuloma cell DNA by the alkaline elution technique. DNA breaks were primarily induced by monofunctional alkylating agents (procarbazine, methylmethane sulfonate, cyclophosphamide, and N-methyl-N'-nitro-N-nitrosoguanidine), and they were characteristic for each compound. DNA from animals treated with polyfunctional alkylating agents (triethylenemelamine, mitomycin C, and busulfan) and DNA-intercalating agents (adriamycin, proflavin, and acriflavin) showed a variable degree of resistance to methylmethane sulfonate-induced DNA breakage. Resistance was greater with the former agents. (38 refs)

- 79-5578 Studies on the Distribution and Metabolism of N -[^{14}C]Nitrosopyrrolidine in Mice. (Eng) Johansson-Brittebo, E. (Dept. Toxicology, Univ. Uppsala, Uppsala, Sweden); Tjalve, H. *Chem Biol Interact* 25(2/3): 243-253; 1979.

Pretreatments (ip) with pyrazole (200 mg/kg), ethanol (3.1 g/kg), hialamide (500 mg/kg), or diethyldithiocarbamate (350 mg/kg) strongly depressed the exhalation of $^{14}\text{CO}_2$ and the incorporation of radioactivity in the acid-insoluble fraction of the liver in mice injected with N -[^{14}C]nitrosopyrrolidine (^{14}C -NP, 2.0 μCi ; 0.6 mg/kg). Whole-body autoradiography performed with hemisections of pretreated and non-pretreated mice at -80 C (to prevent evaporation of the volatile NP) and with dry tape-sections (to localize the nonvolatile metabolites) indicated a uniform distribution of the nonmetabolized NP in the tissues. At the shortest survival intervals (1 and 5 min), a high level of metabolites was found in the liver, the tracheobronchial and nasal mucosa and Harder's gland, indicating a local formation of metabolites in these tissues. At later survival intervals (0.5-24 hr) metabolites were also found in tissues with a rapid cell turnover and a high rate of protein synthesis and in brown fat; this may reflect incorporation of metabolites via normal biosynthetic pathways. Autoradiography of ^{14}C -NP administered po in mice resulted in distribution pictures similar to those obtained after iv injections. (27 refs)

- 79-5579 Adaptive Response to Alkylating Agents Involves Alteration In Situ of O 6 -Methylguanine Residues in DNA. (Eng) Karran, P. (Dept. Medical Chemistry, Univ. Gothenburg, 40033 Gothenburg, Sweden); Lindahl, T.; Griffin, B. *Nature* 280(5717): 76-77; 1979.

The nature of the error-free repair system that removes O 6 -methylguanine (OMG) residues from *Escherichia coli* DNA alkylated by N-methyl-N-nitrosourea (MNU) was investigated in vitro using [Me- ^3H]MNU-treated *Micrococcus luteus* DNA and cell-free extracts (CFE's) from nonadapted and adapted *E. coli*. The extracts were adapted by growth for 90 min in the presence of 1 $\mu\text{g}/\text{ml}$ N-methyl-N'-nitro-N-nitrosoguanidine, and they possess increased resistance to alkylating agents. The MNU-treated DNA was preincubated for 16 hr at 80 C in neutral soln to release

purines methylated at the 7 and 3 positions and yet retain the double-stranded DNA structure. When DNA containingq OMG was incubated with nonadapted and CFE's, precipitated with cold ethanol or trichloroacetic acid, and subjected to mild acid hydrolysis to release free purines, paper chromatography of the hydrolysate demonstrated that with increasing amounts of adapted CFE in the reaction mixtures, decreasing amounts of OMG were recovered. Moreover, no OMG was released in an ethanol- or acid-soluble form at the end of the incubation period, and only after the hydrolysis step was the radioactivity in the OMG residues converted to a volatile product (presumably methanol), indicating that the repair system in adaptation either transfers the O 6 -methyl group to another site or that OMG residues are destroyed in situ (eg, by ring cleavage). When the radioactive material in reaction mixtures treated with an adapted CFE (90% disappearance of OMG from DNA) was treated with Pronase (2 mg/ml) or pancreatic RNase (100 $\mu\text{g}/\text{ml}$), no ethanol-soluble radioactivity was released. When this material was treated with pancreatic DNase I (100 $\mu\text{g}/\text{ml}$), however, 80% of the radioactivity was converted to ethanol-soluble form. Similar results were obtained in control experiments with DNA incubated with nonadapted CFE. Thus, the radioactive methyl groups in the ethanol-precipitable material generated from OMG residues by treatment with the adapted CFE remain in DNA and are not transferred to a protein or RNA molecule. Mutants defective in the adaptive response were isolated, and the inducible enzyme responsible for adaptation appears to be the product of a single gene. (11 refs)

- 79-5580 Thioether Concentration and Mutagenicity of Urine from Cigarette Smokers. (Eng) van Doorn, R. (Inst. Pharmacology and Toxicology, Univ. Nijmegen, Nijmegen, Netherlands); Bos, R. P.; Leijdekkers, C. M.; Wagenaar-Zegers, M. A.; Theuvs, J. L.; Henderson, P. T. *Int Arch Occup Environ Health* 43(3): 159-166; 1979.

The mutagenicity of thioethers for *Salmonella typhimurium* strain TA1538 and the urinary excretion of these compounds by smokers and nonsmokers were studied. The urinary concentrations of thioethers increased significantly in smokers compared with nonsmokers, and they increased with the number of cigarettes smoked per day. Compared with nonsmokers, persons smoking up to 10 cigarettes/day showed no increase in the excretion of urinary mutagens, but the excretion of mutagens was significantly increased in persons smoking >10 cigarettes/day. The increase in urinary mutagens was not reflected by a concomitant increase in urinary thioethers. Urinary thioether and mutagen excretion was monitored in a single subject who increased the number of cigarettes smoked/day from 0 to 20 over a 20-day period. The appearance in the urine of mutagens inhaled during smoking and excreted unchanged or as metabolites correlated fairly well with the number of cigarettes smoked that day. However, excretion of thioethers responded more slowly to changes in the number of cigarettes smoked. The data indicate that cigarette smoking may interfere with the results of tests used to monitor occupational exposure to potential alkylating agents. (20 refs)

- 79-5581 Mutagenic Activities of Hydroperoxythymine Derivatives, Products of Radiation and Oxidation Reactions. (Eng) Wang, S. Y. (Dept. Environmental Health Sciences, Sch. Hygiene and Public Health, Johns Hopkins Univ., 615 N. Wolfe St., Baltimore, MD 21205); Hahn, B. S.; Batzinger, R. P.; Bueding, E. *Biochem Biophys Res Commun* 89(1): 259-263; 1979.

To determine whether the chemical reactivities of the pyrimidine hydroperoxides are correlated with their mutagenicities, the efficacies of *cis*-5,6-dihydro-6-hydroperoxy-5-hydroxythymine (6-TOOH) and 5-hydroperoxymethyluracil (α -TOOH) in the inactivation of *Hemophilus influenzae* transforming DNA were compared. α -TOOH, which is about 10^3 -fold less chemically reactive than 6-TOOH, was approx 10^3 -fold more effective in the biological inactivation. *Salmonella typhimurium* strains TA100 and TA98 were used to determine whether mutations could result from different steric interactions with DNA molecules. In this system, various hydroperoxy derivatives of thymine and thymidine produced by ionizing radiation, near-UV radiation, and certain oxidation reactions were highly mutagenic. In general, the hydroperoxy derivatives required no metabolic activation. If these data reflect the general toxicity of these compounds for humans, radiation products and certain oxidation products should be considered potential human health hazards. (15 refs)

79-5582 Effects of the Comutagens, Harman and Norharman, on the Interaction of a Tryptophan Pyrolysis Product, 3-Amino-1-methyl-5H-pyrido(4,3-b)indole with DNA. (Eng) Lau, P. P. (Dept. Chemistry, Massachusetts Inst. Technology, Cambridge, MA 02139); Luh, Y. *Biochem Biophys Res Commun* 89(1): 188-194; 1979.

Harman and norharman, both of which are comutagens of many chemicals, were tested for their effect on the binding of DNA to 3-amino-1-methyl-5H-pyrido(4,3-b)indole (Trp-P-2), a potent mutagen found with harman and norharman in the pyrolysate of tryptophan. Neither comutagen significantly affected the binding of Trp-P-2 to DNA in the absence of microsomal proteins, although a slight decrease in affinity occurred at extremely high concentrations (1 mM) of harman. A covalent binding study revealed that both comutagens inhibited rather than enhanced the binding of Trp-P-2 to DNA in the presence of 3-methylcholanthrene-induced male Fischer rat liver microsomes. The mutagenesis of Trp-P-2 has also been shown to be inhibited by harman and norharman. Thus, the inhibiting action of these compounds is largely enzymatic in contrast to noncovalent binding. It is suggested that the so-called "enhancing" effect of the comutagens on mutagenesis under an unfavorable enzymatic condition might be an artifact of the assay method. (16 refs)

79-5583 A Collaborative Dominant Lethal Study of Triethylenemelamine in the Rat. (Eng) Moreland, F. M. (Div. Toxicology, Food and Drug Admin., Washington, DC 20204); Kilian, D. J.; Palmer, K. A.; Springer, J. A.; Green, S.; Legator, M. S. *Toxicol Appl Pharmacol* 49(1): 161-170; 1979.

A collaborative dominant lethal study of the known mutagen triethylenemelamine (TEM) was conducted in male rats. Six laboratories were supplied with animals from a common source and with TEM of the same lot number in an attempt to guarantee uniformity of strain and drug effect. Male Sprague-Dawley rats which were proven breeders were divided into five groups of 15 animals each and were given a single ip injection of TEM at 0 (saline), 0.125, 0.250, 0.375, or 0.500 mg/kg, respectively. After the injection, each male was housed with two virgin females (200 g) each week for a 10-week period. The females were sacrificed by asphyxiation 14 days after the midweek of cohousing, and corpora lutea were counted and the uterine contents examined. The results showed a highly significant difference among laboratories for the number of corpora lutea per pregnant female and for preimplanta-

tion losses over all doses and weeks. Variability among laboratories was least for total implants in both treated and control groups and dead implants in the control group. Although the variation was great between laboratories with respect to the several parameters considered, the results obtained by each laboratory did show that TEM has a significant mutagenic effect in the dominant lethal test. (13 refs)

79-5584 In Vivo Alkylation of Foetal, Maternal and Normal Rat Tissue Nucleic Acids by 3-Methyl-1-phenyltriazen. (Eng) Margison, G. P. (Paterson Labs., Christie Hosp. and Holt Radium Inst., Manchester M20 9BX, England); Likhachev, A. J.; Kolar, G. F. *Chem Biol Interact* 25(2/3): 345-353; 1979.

The carcinogen 3-methyl-1-phenyltriazen (MPT: 80 mg/kg) was administered sc to normal or pregnant BD VI rats, and DNA and RNA were isolated from various tissues after 8 or 15 hr, respectively. Sephadex G-10 chromatography of DNA hydrolysates showed the presence of 7-methylguanine in all tissues examined, including that of the brain, one of the target organs for tumor induction. The amounts of the minor product O⁶-methylguanine were characteristic of an SN₁ reaction mechanism. Dowex-50 chromatography of RNA hydrolysates showed the presence of 7-methylguanine and of another minor product, 3-methylcytosine. The relative amounts, both of methylated bases in the individual nucleic acids and of 7-methylguanine in DNA and RNA were similar to those found previously after administration of 3,3-dimethyl-1-phenyltriazen (DMPT). This suggests the involvement of a common alkylating intermediate. De novo incorporation of radioactivity into purine bases was detected in both DNA and RNA, although the levels were not related to the amounts of methylation. The results show that MPT is sufficiently stable to alkylate nucleic acids in vivo, and they are consistent with the hypothesis that this reaction is a prerequisite for tumor induction. Furthermore, they support the proposal that MPT is the active intermediate in the induction of tumors by DMPT. (22 refs)

79-5585 Inhibition of DNA Synthesis by Nitroheterocycles. I. Correlation with Half-Wave Reduction Potential. (Eng) Olive, P. L. (Radiobiology Section, Johns Hopkins Oncology Center, 601 North Broadway, Baltimore, MD 21117). *Br J Cancer* 40(1): 89-93; 1979.

Twenty-one nitroheterocycles, including metronidazole, misonidazole, and AF-2, were tested for their ability to inhibit DNA synthesis in mouse L-929 cells growing in culture. All tested drugs inhibited the rate of ³H-thymidine incorporation into L cells following drug treatment for 4 hr under aerobic conditions. Only four drugs reached their limits of solubility before ³H-thymidine uptake was inhibited by 50% or more. For the remaining 17, the log of the concentration producing 50% inhibition of incorporation was directly correlated with the half-wave reduction potential of the compound. (17 refs)

79-5586 Absence of Genotoxic Effects of Metronidazole and Two of Its Urinary Metabolites on Human Lymphocytes In Vitro. (Eng) Lambert, B. (Dept. Clinical Genetics, Karolinska Hosp., 104 01 Stockholm, Sweden); Lindblad, A.; Ringborg, U. *Mutat Res* 67(3): 281-287; 1979.

The genotoxicity of the antiprotozoan agent metronidazole [1-(2-hydroxyethyl)-2-methyl-5-nitroimidazole] and two of its major human urinary excretion products, 2-methyl-5-nitroimidazole-1-yl acetic acid and 1-(2-hydroxyethyl)-2-hydroxymethyl-5-nitroimidazole, was tested in human lymphocytes in vitro by analysis of chromosome aberrations, sister-chromatid exchanges and DNA-repair synthesis. The positive control compounds methyl methanesulfonate (MMS) and nitrogen mustard (NH_2) showed significant genotoxic activity in these tests. No such activity of metronidazole and its two metabolites was detected in concentrations up to 1,000 $\mu\text{g}/\text{ml}$ (5.8×10^{-3} M). These three compounds also had no influence on the DNA-repair synthesis induced by MMS and HN_2 . The results suggest that metronidazole and its urinary metabolites have no direct genotoxic effect on human lymphocytes in vitro. (26 refs)

- 79-5587 Absence of Chromosomal Damage in the Lymphocytes of Patients Treated with Metronidazole for *Trichomoniasis vaginalis*. (Eng) Hartley-Asp, B. (AB Leo, Res. Labs., Helsingborg, Sweden). *Toxicol Lett* 4(1): 15-19; 1979.

The peripheral blood lymphocytes of 12 patients (19-48 yr old) receiving metronidazole (200 mg tid for 7 days) for *Trichomoniasis vaginalis* infections were analyzed for chromosome aberrations. Samples were taken before, during, and 3 wk after completion of treatment, with each patient acting as her own control. No increase in chromosome aberration frequency was found for any aberration type, either for the individual or for the group means. Thus, short-term metronidazole treatment did not produce any clastogenic effect on human lymphocytes in vivo. (14 refs)

- 79-5588 The Action of Rat Cytosol Enzymes on Some Methylated Nucleic Acid Components Produced by the Carcinogenic N-Nitroso Compounds. (Eng) O'Connor, P. J. (Paterson Labs., Christie Hosp. and Holt Radium Inst., Manchester M20 9BK, England); Saffhill, R. *Chem Biol Interact* 26(1): 91-102; 1979.

The stability of several O- and N-methylated nucleic acid derivatives was examined in the presence of cytosol extracts from a variety of male Wistar rat tissues. An activity capable of demethylating O⁶-methyldeoxyguanosine was readily detectable in all tissues examined. Arranged in approx order of decreasing specific activity, these tissues are as follows: small intestine, spleen, kidney, lung, liver, skin, heart, and brain. The in vitro requirements for the activity derived from liver and the observations that O⁶-methylguanine and its deoxynucleoside 5'-monophosphate are insensitive to the action of these extracts suggest that this activity may be due to an enzyme that resembles adenosine deaminase. In contrast to the ready degradation of O⁶-methyldeoxyguanosine, the corresponding ethyl derivative was degraded much more slowly. There was no evidence of degradation of the O²- and O²-methyldeoxythymidines, even after exposure of these components to cytosol enzymes for up to 90 min. Similarly, no demethylation of 3-methyldeoxycytidine, 3-methyldeoxythymidine, 1-methyldeoxyadenosine, and 7-methyldeoxyguanosine was detected. (33 refs)

- 79-5589 Quantitation of the Adaptive Response to Alkylating Agents. (Eng) Robins, P. (Imperial Cancer Res. Fund,

Mill Hill Labs., Burtonhole Lane, London NW7, England); Cairns, J. *Nature* 280(5717): 74-76; 1979.

Experiments were carried out to investigate the nature of the fast and slow reactions in the adaptive response of *Escherichia coli* AB1157 to treatment with alkylating agents, particularly N-methyl-N'-nitro-N-nitrosoguanidine (MNNG), that convert guanine to O⁶-methylguanine (OMG). Adapted and nonadapted bacterial cultures were used in experiments involving challenge with 10 or 50 $\mu\text{g}/\text{ml}$ 3H-MNNG for 2 min; adapted cells had been previously exposed to 0.5 $\mu\text{g}/\text{ml}$ MNNG for 90 min. When adapted bacteria were challenged with the 10- μg dose and nonadapted bacteria with the 50- μg dose (so that the OMG content of the two cultures was the same after challenge and both cultures were outgrown in the absence of MNNG, OMG was lost at equal rates from both cultures. If the challenge dose was the same, however, adapted bacteria lost OMG sooner than did nonadapted bacteria. Hence, adapted and nonadapted bacteria appear to differ only in the presence of the fast reaction; the slow reaction seems to be some constitutive form of repair that cannot be enhanced by adaptation. When adapted and nonadapted bacteria were challenged and then outgrown at 37 C, at 0 C, or at 37 C in the presence of 100 $\mu\text{g}/\text{ml}$ chloramphenicol, the fast reaction but not the slow reaction occurred, demonstrating that the fast reaction is carried out by gene products that have accumulated during adaptation and are used up during challenge, but the slow reaction represents the induced synthesis and immediate action of these same gene products. The fact that the molecules that remove OMG units appear to be used up in the response could explain two phenomena: (1) large doses of alkylating agents inhibit the capacity of cells to handle subsequent small doses of these agents and (2) certain nitrosamines exhibit high carcinogenicity in animals (in which doses are usually high) but low mutagenicity in the Ames test (in which doses are usually low); the first system may be saturated, whereas the second one is not. - 79-5590 Inhibition of Nitroso Chemical Carcinogen Activation of Rat Hepatic Guanylate Cyclase by Anticancer Agents. (Eng) Vesely, D. L. (Div. Endocrinology and Metabolism, Dept. Medicine, Univ. Arkansas Medical Sch., 4301 W. Markham, Little Rock, AR 72201); Levey, G. S. *Oncology* 36(3): 122-126; 1979.

The effect of three major classes of anticancer chemotherapeutic agents, antimetabolites (methotrexate and 6-mercaptopurine), antitumor antibiotics (adriamycin and actinomycin D), and alkylating agents (cytoxan, uracil mustard, isophosphamide, chlornaphazine, and 1-propanol-3,3'-iminodimethane sulfonate) on the activation of guanylate cyclase (GC) by nitroso chemical carcinogens was examined. The anticancer chemotherapeutic agents noncompetitively blocked the activation of rat hepatic GC by N'-nitro-N-nitroso-N-propylguanidine (NNPG) and hydrazine. Adriamycin, methotrexate, and uracil mustard were the most effective inhibitors, completely abolishing the effect of 1 mM NNPG on GC activity. The remainder of the agents abolished the NNPG activation of GC 40%-70%. Since a previously described GC inhibitor has been shown to terminate the growth of an undifferentiated prostatic cancer in tissue culture, the present data may indicate that one of the mechanisms by which anticancer chemotherapeutic agents exert their effects is by inhibition of tumor GC activity. (21 refs)

- 79-5591 Intestinal Metaplasia and Adenocarcinoma Induced in the Stomach of Rats by N-Propyl-N'-nitro-N-

nitrosoguanidine. (Eng) Sasajima, K. (Biochemistry Div., Natl. Cancer Center Res. Inst., Tsukiji 5-1-1, Chuo-ku, Tokyo, Japan); Kawachi, T.; Matsukura, N.; Sano, T.; Sugimura, T. *J Cancer Res Clin Oncol* 94(2): 201-206; 1979.

The effects of long-term po administration of N-propyl-N'-nitro-N-nitrosoguanidine (PNNG), the propyl derivative of MNNG, were determined in Wistar Rats. PNNG was administered to the rats at a concentration of 59.5 µg/ml in the drinking water for 4, 8, or 12 mo, and the rats were killed in the 15th month. Intestinal metaplasia was induced in the glandular stomachs of 25%, 75%, and 83% of the rats treated for 4, 8, and 12 mo, respectively. Metaplastic glands were found in the pyloric region, especially near the pyloric ring. These glands contained goblet cells and columnar cells with striated borders. No tumors were found in the stomach of rats after 4 mo of treatment, but adenomas (3/15 rats) were found after 8 mo of treatment, and both adenomas (5/6) and adenocarcinomas (2/6) were found after 12 mo of treatment. PNNG is a weaker carcinogen than N-methyl-N'-nitro-N-nitrosoguanidine. The present system should be useful in further studies of intestinal metaplasia and of the relationship between intestinal metaplasia and gastric carcinoma. (10 refs)

79-5592 Interactions of the Carcinogen 4-Nitroquinoline 1-Oxide with the Non-protein Thiols of Mammalian Cells. (Eng) Varnes, M. E. (Div. Radiation Biology, Dept. Radiology, Case Western Reserve Univ., Cleveland, OH 44106); Biaglow, J. E. *Cancer Res* 39(8): 2960-2965; 1979.

Some of the factors that influence the reaction of 4-nitroquinoline 1-oxide (4-NQO) with the nonprotein thiols (NPSH) of whole cells were investigated. 4-NQO rapidly depleted the NPSH from Ehrlich ascites tumor cells and V79 Chinese hamster fibroblasts. The effects of NPSH on 4-NQO metabolism were studied by measuring 4-hydroxyaminoquinoline 1-oxide (4-HAQO) formation, cyanide ion-insensitive oxygen consumption, and reduction of ferricytochromes $c + c_1$ in normal cells and in cells pretreated with the thiol reagent N-ethylmaleimide. Removal of thiols before treatment with 4-NQO resulted in an increased production of 4-HAQO and an increased production of nitro radicals. The NPSH thus appeared to play a significant role in 4-NQO detoxification. Glutathione, when present in culture medium during 4-NQO treatment, protected V79 cells from 4-NQO toxicity. Several mechanisms for the reaction of 4-NQO with intracellular NPSH were indicated. Both V79 and Ehrlich cells contained appreciable amounts of glutathione S-transferase, which catalyzes the nucleophilic substitution of the nitro group of 4-NQO with thiols. Greater thiol loss under oxic than under hypoxic conditions suggested oxidation by superoxide, peroxide, or hydroxyl radical formed during 4-NQO reduction. In addition, reaction of thiols with nitro radicals or with nitrosoquinoline 1-oxide was indicated by the inhibitory effect of glutathione on oxygen consumption in solns of 4-NQO and sodium ascorbate. (27 refs)

79-5593 Possible Use of Fish and Amphibia for Detecting the Carcinogenic Effect of Nitrosomorpholine and Its Chemical Precursors. (Rus) Khudolei, V. V. (Lab. Chemical Carcinogens, N. N. Petrov Res. Inst. Oncology, Leningrad, USSR); Anikin, I. V.; Sirenko, O. A.; Pliss, G. B. *Vopr Onkol* 25(6): 70-75; 1979.

The carcinogenic effect of nitrosomorpholine (NM) and its chemical precursors was evaluated in frogs (*Rana temporaria*) and

aquarium fish (*Danio rerio* and *Xiphophorus helleri*) in two series of experiments. In series I, frogs were kept in water containing 6 mg/liter of NM, 40 mg/liter of sodium nitrite (SN), 20 mg/liter of morpholine, or SN + morpholine; duration of exposure ranged from 44 to 70 wk. The first NM-induced tumors were detected at 7 wk (av latent period of tumor development was 24 wk); 17/37 surviving frogs had tumors (7 had liver tumors and 10 had generalized tumors of the blood system). Frogs exposed to SN or morpholine alone were free of tumors, but 10/34 frogs exposed to SN + morpholine developed tumors (1 had a benign tubular-trabecular hepatic adenoma, 4 had hepatocellular carcinomas (HCC's), and 5 had generalized hemoblastoses). The av latent period of tumor development was 32 wk. In series II, fish were kept in water containing 0.1-0.3 mg/liter of NM, 7.3 mg/liter of SN, 3.6 mg/liter of morpholine, or SN + morpholine; duration of exposure ranged from 28 to 52 wk. Of 24 *D. rerio* fish exposed to NM, 8 developed tumors (av latent period was 16-22 wk). There were 7 HCC's, 4 adenocarcinomas of the intestine, and 1 mesenchymoma. Of 17 *X. helleri* fish exposed to NM, 5 developed HCC's (av latent period was 23 wk). Both species exposed to SN or morpholine alone were free of tumors. Exposure to SN + morpholine induced tumors in 2/9 *D. rerio* fish (2 HCC's, and 1 adenomatous polyp of the intestine; av latent period was 42 wk) and in 2/5 *X. helleri* fish (2 HCC's; av latent period was 42 wk). The use of aquatic animals as indicators of water pollution by nitrosamines and their precursors is discussed. (12 refs)

79-5594 Chemical Reactivities and Oncogenicities of a Series of N-Hydroxyheterocycles. (Eng) Lee, T. C. (Memorial Sloan-Kettering Cancer Center, 1275 York Ave., New York, NY 10021); Teller, M. N.; Budinger, J. M.; Klotzer, W.; Brown, G. B. *Chem Biol Interact* 25(2/3): 369-372; 1979.

Because the oncogenicity of certain N-hydroxypurines was found to be paralleled by a unique chemical reactivity of their ester derivatives, ie, the esters undergo elimination-substitution (SN1') reactions to yield 8-substituted xanthines, a series of six ring analogs of 3-hydroxyxanthine was investigated to determine the structural features required for this type of SN1' reactivity. Selected compounds from the series were also assayed for carcinogenicity. Comparisons of the reactivities of the six compounds from previous reports showed that the ability of each compound to undergo an SN1' reaction is: 1-hydroxy-2,4-dioxypyrrrolopyrimidine (I) > 3-hydroxyxanthine (II) > 3-hydroxy-2-oxopurine (III) > the N-hydroxy derivative of quinazoline (IV) > the N-hydroxy derivative of pyridopyrimidine > the N-hydroxy derivative of pteridine. This order agrees with predictions made from the relative π -electron densities of the pyrrole, imidazole, benzene, pyridine, and pyrazine ring systems, with III being placed after II because of its lack of a 6-oxo group. Since only the π -electron-excessive ring systems exhibit high reactivity, only I, II, and III were assayed for carcinogenicity along with 1-hydroxyuracil, the parent pyrimidine derivative. The compounds were administered sc 3x/wk for 8 wk to groups of 20 male CD rats that were followed for 18 mo. The failure of I to induce any tumors at a dose of 1.0 mg/injection may be due to its extreme reactivity. Compound II induced tumors in 108/115 rats at a dose of 1.0 mg/injection and in 32/77 rats at a dose of 0.1 mg/injection. Compound III was weakly oncogenic (3/20 rats had tumors), a result that may be due to its susceptibility to xanthine oxidase, which is present in sc tissues. 1-Hydroxyuracil induced tumors in 1/18 rats. It appears that the appropriate degree of reactivity in an SN1' reaction is peculiar to the purine ring. (23 refs)

79-5595 Hormone Secretion by Dispersed Cell Cultures of Human Pituitary Adenomas: Effects of Theophylline,

Thyrotropin-releasing Hormone, Somatostatin, and 2-Bromo- α -ergocryptine. (Eng) Adams, E. F. (Endocrine Unit, Dept. Medicine, Royal Postgraduate Medical Sch., Hammersmith Hosp., London, W12 OHS, England); Brajkovich, I. E.; Mashiter, K. *J Clin Endocrinol Metab* 49(1): 120-126; 1979.

A dispersed cell culture system was used to examine basal and modulated secretion of prolactin (PRL) and growth hormone (GH) by human somatotrophic (ST), lactotropic (LT), and mixed ST-LT pituitary adenomas. The 24-hr secretion of PRL by a normal pituitary and by a LT and a mixed adenoma increased with time in culture. The secretion rate from the mixed adenoma was 18-fold higher on day 20 than on day 1, with 225 μ g PRL being produced from 4×10^5 cells. PRL secretion was still elevated after 36 days of culture. GH secretion always decreased rapidly from day 1. Initial GH secretion in cultures of a ST adenoma was 18 times of that from the same number of normal pituitary cells. Theophylline (10^{-2} M) significantly stimulated GH secretion by ST and mixed adenoma cells during a 4-hr incubation after 4 and 28, but not 49, days in culture. PRL secretion was only stimulated at 28 days. Thyrotropin-releasing hormone stimulated PRL and GH secretion from adenomas in a dose-dependent manner, with 10 nanograms (ng)/ml being max. Somatostatin alone at doses up to 100 ng/ml had no consistent effect on GH secretion, but it completely blocked the twofold stimulation induced by 10^{-2} M theophylline. 2-Bromo- α -ergocryptine increasingly inhibited basal PRL and GH secretion up to the max dose used (10 μ g/ml), and it virtually abolished the theophylline-induced stimulation of GH and PRL secretion at this dose. These results show that dispersed cell cultures of human pituitary adenomas can be satisfactorily maintained for at least 28 days and that they autonomously secrete PRL but not GH during this period. The modulation of PRL and GH secretion by various agents indicates the value of this technique for the direct study of functioning human pituitary adenomas. (32 refs)

79-5596 Caffeine, Cyclic Nucleotides, and Breast Disease. (Eng) Minton, J. P. (Dept. Surgery, Ohio State Univ. Coll. Medicine, 410 W. 10th Ave., Columbus, OH 43201); Foelcking, M. K.; Webster, D. J.; Matthews, R. H. *Surgery* 86(1): 105-109; 1979.

The clinical effect of removing methylxanthine (MX) from the diets of 47 women with clinical fibrocystic disease of the breast was studied. Twenty of the patients abstained totally from MX consumption. All experienced a headache for 1-7 days after beginning abstinence. Of these 20 women, 13 experienced complete disappearance of all palpable breast nodules and other symptoms within 1-6 mo after eliminating MX from their diets, whereas only 1/27 of women who continued MX consumption experienced disease resolution ($p < 0.001$). The mean age of the 13 women who discontinued MX consumption and experienced disease resolution was 35 yr, compared with 45 yr in the group who ceased MX consumption but did not experience disease resolution. Cyclic AMP levels in the fibroadenomatous tissue increased as the deviation of the tissue from normal increased. Elevations in cyclic guanosine monophosphate were more transient. Long-term follow-up studies indicated that breast disease returned when MX consumption was resumed, but it remained resolved when abstinence from MX was continued. The possibility that MX consumption is related to the development of malignancy should be considered. (12 refs)

79-5597 A Carcinogen with a Bridged Bay Region: Synthesis, X-Ray Structure, and Biological Activity of 15,16-

Dihydro-1,11-methanocyclopenta(α)-phenanthren-17-one. (Eng) Bhatt, T. S. (Chemistry Lab., Imperial Cancer Res. Fund, Lincoln's Inn Fields, London WC2A 3PX, England); Coombs, M. M.; Kissonerghis, A. M.; Clayton, A. F.; McPartlin, M. *J Chem Soc Chem Commun* 10: 433-434; 1979.

15,16-Dihydro-1,11-methanocyclopenta(α)phenanthren-17-one was synthesized, and its x-ray structure was determined. Although it has a bridged bay region, it is a carcinogen. (6 refs)

79-5598 Substitutional Effects of Styrene Oxides on Survival and Mutation Induction in Cultured Chinese Hamster Cells (V-79)*. (Eng) Sugiura, K. (Inst. Ecotoxicology, Gakushuin Univ., Toshima-ku, Tokyo 171, Japan); Maeda, A.; Goto, M. *Chemosphere* 8(6): 369-372; 1979.

A study of the effects of 3,4-dimethyl-, p-methyl-, m-chloro-, and unsubstituted styrene oxide on survival and on the induction of 6-thioguanine-resistant mutations revealed that mutagenicity and lethality increased in the order: styrene oxide < m-chlorostyrene oxide < p-methylstyrene oxide < 3,4-dimethylstyrene oxide. There was an inverse correlation between LD₅₀ values and retention time. (10 refs)

79-5599 Inhibition of Promutagen Activation by the Antioxidants Butylated Hydroxyanisole and Butylated Hydroxytoluene. (Eng) McKee, R. H. (Litron Labs., Ltd., Ontario Res. Inst., 1351 Mt. Hope Ave., Rochester, NY 14620); Tometsko, A. M. *J Natl Cancer Inst* 63(2): 473-477; 1979.

Butylated hydroxyanisole (BHA) and butylated hydroxytoluene (BHT) exhibited antimutagenic activity in the *Salmonella typhimurium* reversion test. Both BHA and BHT reduced the revertant yields induced by chemicals requiring metabolic activation for effectiveness. However, they did not affect reversion induced by direct-acting mutagens. These results suggest that BHA and BHT may inhibit metabolic activation processes, and they demonstrate that the *S. typhimurium* reversion test may be used to identify inhibitors of neoplasia. (33 refs)

79-5600 Effect of 2(3)-tert-Butyl-4-hydroxyanisole Administration on the Activities of Several Hepatic Microsomal and Cytoplasmic Enzymes in Mice. (Eng) Cha, Y. N. (Dept. Pathobiology, Johns Hopkins Medical Institutions, Baltimore, MD 21205); Bueding, E. *Biochem Pharmacol* 28(12): 1917-1921; 1979.

The effect of 2(3)-tert-butyl-4-hydroxyanisole (BHA) on hepatic microsomal and cytoplasmic enzyme activities was studied in CD-1 mice. When the mice were fed a powdered diet containing 0.75% BHA (wt/wt), the activities of several hepatic enzymes increased markedly. This was associated with increased liver wts and total protein contents, especially of the microsomal and cytosol fractions. Although the specific level of cytochrome P-450 was decreased slightly in the microsomes, the specific level of cytochrome b₅ and the specific activities of the cytochrome c reductases (NADPH- or NADH-dependent) were increased twofold. There was a slight decrease in the specific activities of aminopyrine demethylase and benzo(a)pyrene hydroxylase, but both aniline hydroxylase and uridine diphosphate (UDP)-glucuronyltransferase activities were increased (2.7- and 4.6-fold,

respectively). The specific activity of a microsomal membrane marker enzyme, glucose-6-phosphatase, was decreased slightly (25%). In the cytosol fraction, the specific activities of glucose-6-phosphate dehydrogenase and of UDP-glucose dehydrogenase were increased 3.8- and 6.1-fold, respectively. Differences were noted in the time courses of the increase and decrease in these enzyme activities after initiation and discontinuation of BHA treatment. (38 refs)

- 79-5601 Nasocytologic Examination of Wood Industry Workers. (Eng) Drettner, B. (Dept. Otolaryngology, Univ. Hosp., Huddinge, Sweden); Stenkvist, B. *Acta Otolaryngol [Suppl] (Stockh)* 360: 122-123; 1979.

Two methods for the field examination of furniture industry workers (nasal rinsing and direct sample-taking from the middle meatus) were evaluated for their applicability to the early diagnosis of ethmoidal cancer. Among 715 Swedish wood workers, direct sampling proved superior to the rinsing method in that samples obtained by the former method contained up to 88% cylinder cells as compared with only 2% obtained by the latter method. No cancerous or precancerous changes could be identified in any of the workers examined. (6 refs)

- 79-5602 The Interaction of Styrene Oxide with Hepatic Cytochrome P-450 In Vitro and Effects of Styrene Oxide Inhalation on Xenobiotic Biotransformation in Mouse Liver and Kidney. (Eng) Vainio, H. (Dept. Industrial Hygiene and Toxicology, Inst. Occupational Health, Haartmaninkatu 1, SF-00290 Helsinki 29, Finland); Elovaara, E. *Biochem Pharmacol* 28(13): 2001-2004; 1979.

During the 5-day recovery period after acute inhalation intoxication with styrene oxide (SO: 6 hr/day, 3 days at 200, or 100 ppm), a transient rise in mouse liver and kidney microsomal 7-ethoxycoumarin O-deethylase activity paralleled changes in cytochrome P-450 levels. Microsomal epoxide hydratase and Uridine diphosphate-glucuronosyltransferase activities were unaffected. In the presence of hepatic microsomes from phenobarbital (PB)-treated mice, SO produced a characteristic Type I difference spectrum. SO binding is catalyzed by more than one type of P-450 hemoprotein, but predominantly by PB-induced cytochrome P-450. In PB-pretreated microsomes, SO had two spectral dissociation constants, 0.05 and 0.4 mM. (18 refs)

- 79-5603 Cytogenetic Activity of Some Common Antioxidants and Their Interaction with X-Rays. (Eng) Kaul, B. L. (Regional Res. lab., Jammu, Tawi, 180001, India). *Mutat Res* 67(3): 239-247; 1979.

The cytogenetic activity of butylated hydroxyanisole, butylated hydroxytoluene, propyl gallate, and p-methoxyphenol, phenolic antioxidants widely used to preserve and stabilize foods rich in fats and oils, was investigated in barley seeds and onion root tips. The treatments reduced seed germination and induced a significant amount of seedling injury. Only the p-methoxyphenol treatments produced a moderate amount of chromosome aberrations. Being strong antioxidants, it was expected that pretreatment of the two plant systems with these compounds would reduce the cytogenetic damage caused by x-radiation. Contrary to expectation, however, radiation damage, measured as seed and seedling lethality and

chromosome aberrations, was increased significantly. Postirradiation treatment with the antioxidants also increased the radiation damage. The damage was, however, reduced by postirradiation treatment with ATP. (16 refs)

- 79-5604 Elevation of Extrahepatic Glutathione S-Transferase and Epoxide Hydratase Activities by 2(3)-tert-Butyl-4-hydroxyanisole. (Eng) Benson, A. M. (Dept. Pharmacology and Experimental Therapeutics; Johns Hopkins Univ. Sch. Medicine, Baltimore, MD 21205); Cha, Y. M.; Bueding, E.; Heine, H. S.; Talalay, P. *Cancer Res* 39(8): 2971-2977; 1979.

A study was made of the effects of 2(3)-tert-butyl-4-hydroxyanisole (BHA: 7.5 g/kg diet) on glutathione S-transferase (GST) and microsomal epoxide hydratase (EH) levels and on the concentrations of nonprotein thiol compounds in extrahepatic tissues of female CD-1 mice and male Sprague-Dawley rats. BHA resulted in elevated GST and EH activities in multiple extrahepatic tissues of the mice and rats. In mice, GST specific activities in cytosol doubled in the lung and stomach and increased to 15 times control levels (with 1,2-dichloro-4-nitrobenzene as substrate) in the small intestine. Microsomal EH specific activity toward styrene oxide doubled in the mouse colon and stomach and increased to nearly six times control levels in the small intestine. These enzymes were enhanced in several other mouse tissues and in rat small intestine, kidney, and lung. In mice, BHA increased the concentrations of nonprotein sulfhydryl compounds in the mucosa of several digestive tract tissues as well as in the urinary bladder. EH is a detoxifying enzyme that inactivates numerous mutagenic epoxides. However, elevation of EH activity may not necessarily exert a protective function in the case of all arene oxides, since at least some forms of this enzyme catalyze an essential step in the formation of the carcinogenic diol-epoxides of benzo(a)pyrene. The enhancement by BHA of extrahepatic GST activities and nonprotein sulfhydryl levels and possibly, extrahepatic EH activity may be an important factor in the mechanisms by which this antioxidant protects against chemical carcinogenesis. (71 refs)

- 79-5605 Chromosome Aberrations and Sister Chromatid Exchange in Laboratory and Factory Workers and Their Children. (Eng) Funes-Cravioto, F. (Dept. Clinical Genetics, Karolinska Hosp., S-104 01 Stockholm 60, Sweden); Zapata-Gayon, C.; Kolmodin-Hedman, B.; Lambert, B.; Lindsten, J.; Norberg, E.; Nordenskjold, M.; Olin, R.; Swenson, A. *In: Mutagen-induced Chromosome Damage in Man. Proceedings of a Symposium held in Edinburgh, Scotland, July 7-8, 1977. Medical Research Council (Edinburgh, Scotland): 355 pp.; 275-289; 1978.*

A study was made of the frequency of chromosome aberrations and sister-chromatid exchanges (SCE's) in the cultured lymphocytes of 29 women and 6 men working in laboratories where hormone analyses are performed, in 9 women and 7 men working in various chemical laboratories, and in 22 men working in printing factories, where they were exposed to toluene and benzene. Analyses were also made of the lymphocytes of 14 children whose mothers worked in the hormone analysis laboratories during pregnancy. Cultured lymphocytes from all 73 adult subjects had a significantly increased frequency of chromosome aberrations, mainly chromatid and isochromatid breaks, in comparison with 49 control subjects (42 adults and 7 children). An increase of the same magnitude was also found in the 14 children (aged 4 days-11 yr) of 11 women who had worked in the hormone analysis laboratories

during pregnancy. A significant correlation between age and frequency of chromosome aberrations was noted for the exposed and control children, but not for the adults. The frequency of SCE's was significantly increased in a group of 12 technicians working in laboratories performing hormone analysis. Four of the 14 exposed children also had a significantly increased frequency of SCE's. There was a considerable overlap between exposed and control groups with regard to the frequency of chromosome aberrations and SCE's. The cause and biological significance of these findings are not yet known. (24 refs)

- 79-5606** Natulan Induces Forward Mutations to L-Arabinose-Resistance in *Salmonella typhimurium*. (Eng) Pueyo, C. (Catedra de Genetica, Escuela Tecnica Superior de Ingenieros Agronomos, Universidad de Cordoba, Cordoba, Spain). *Mutat Res* 67(2): 189-192; 1979.

The induction of forward mutations from L-arabinose-sensitivity to L-arabinose-resistance in *Salmonella typhimurium* by natulan is reported, and the roles of the excision-repair system and the lipopolysaccharide barrier in the detection of natulan as a bacterial mutagen are discussed. The bacterial strains, as a result of the mutation *araD531*, are sensitive to L-arabinose and are unable to grow in media with L-arabinose and another carbon source. In the absence of liver microsomes (derived from CD1 male mice), natulan was toxic and slightly increased the mutation frequency of strain SV3. When liver microsomes were incorporated into the assay no activity was detected. The excision-repair deficient strain, SV19, was much more sensitive than SV3 with respect to both lethal and mutagenic effects. The mutation frequency of SV19 expressed as $\text{Ara}^r/10^6$, was >200 with a dose of 20 mg/ml of natulan, while that of SV3 was 2.2 in the absence of microsomes. The lowest dose of natulan which doubled the SV19 spontaneous mutation frequency was 5.8 mg/ml. At the highest concentration tested, 30 mg/ml, the spontaneous mutation frequency increased up to 1,000-fold. In strain SV21, which carries a deep-rough mutation and is excision-repair deficient, the enhanced sensitivity to natulan was negated. The mutation frequency was approx 5 for SV21, while it was approx 4,000 for SV19 with 30 mg/ml of natulan in the absence of microsomes. (13 refs)

- 79-5607** Interaction of 4-Methylbenzaldehyde with Rabbit Pulmonary Cytochrome P-450 in the Intact Animal, Microsomes, and Purified Systems. Destructive and Protective Reactions. (Eng) Patel, J. M. (Dept. Pharmacology, Univ. Florida, Gainesville, FL); Wolf, C. R.; Philpot, R. M. *Biochem Pharmacol* 28(13): 2031-2036; 1979.

General mechanisms involved in the partial destruction of rabbit pulmonary cytochrome P-450 by 4-methylbenzaldehyde (4-MBA) are described. About 50% of rabbit pulmonary cytochrome P-450 is destroyed by treatment of the intact animal, microsomes, or systems reconstituted from purified pulmonary monooxygenase components with 4-MBA. The loss of the cytochrome is accompanied by an equimolar loss of heme. The action of 4-MBA requires the presence of NADPH and O_2 and appears to result from cytochrome P-450-catalyzed metabolism. Selective destruction of one of the known forms of rabbit pulmonary cytochrome P-450 does not account for the lack of complete destruction of pulmonary P-450 by 4-MBA; loss of about 50% of each form of the cytochrome occurs in vivo and in reconstituted systems. However, form II is affected to a greater extent than form I when microsomes are incubated with 4-MBA. The portion of the

cytochrome not degraded by 4-MBA appears to be protected by some factor produced from 4-MBA during the incubation. This factor also protects against complete destruction of the cytochrome by cumene hydroperoxide. (28 refs)

- 79-5608** Mutagenic Effects of Styrene and Styrene Oxide. (Eng) Busk, L. (Dept. General Genetics, Univ. Uppsala, S-750 07 Uppsala, Sweden). *Mutat Res* 67(3): 201-208; 1979.

The mutagenicity of styrene and its presumed metabolite styrene oxide (SO) was tested in the *Salmonella*/liver microsome assay using tester strains TA1535, TA1537, TA1538, TA98, and TA100. At 1-10 micromoles (μmol)/plate, SO was mutagenic to TA1535 and TA100, both in the absence and presence of a rat liver microsome system. Styrene, on the other hand, in the concentration range 10^{-3} to $15 \mu\text{mol}$ /plate, was not mutagenic to any of the tester strains, regardless of the presence or absence of a $9,000 \times g$ supernatant of rat liver homogenate. Two differently induced microsomal fractions were used, one induced with Aroclor 1254 and one with another polychlorobiphenyl mixture, Clophen C. Styrene was negative in both systems. Styrene is presumed to be metabolized to SO, and in an attempt to potentiate the possible mutagenicity of styrene, two inhibitors of SO metabolism were added to the homogenates. They were 1,1,1-trichloropropene 2,3-oxide, an inhibitor of epoxide hydratase, and diethyl maleate, an inhibitor of the glutathione conjugation pathway. This did not result in any mutagenic effect of styrene. It is concluded that in the *Salmonella*/liver microsome test, SO is a mutagenic, whereas its presumed precursor in the presence of a metabolizing system is not. This may indicate that when styrene is tested with a rat liver microsome fraction, the concentration of SO is too low for the compound to be detected as a mutagen. (13 refs)

- 79-5609** Styrene Induced Modifications of Some Rat Liver Enzymes Involved in the Activation and Inactivation of Xenobiotics. (Eng) Lambotte-Vandepaer, M. (Lab. Biototoxicology, Catholic Univ. Louvain, Sch. Pharmacy, U.C.L-73.69, 1200 Brussels, Belgium); Bogaert, M. D.; de Meester, C.; Noel, G.; Poncelet, F.; Roberfroid, M.; Mercier, M. *Biochem Pharmacol* 28(10): 1653-1659; 1979.

Male Wistar rats were injected ip with single doses of styrene (10,000, and 500 mg/kg). Its effects on the kinetic parameters of liver microsomal monooxygenases and epoxide hydratase were investigated and compared with those produced by ethylbenzene (EB: 100 mg/kg), the vinyl-saturated analog of styrene, and by phenobarbital (PB: $2 \times 80 \text{ mg/kg}$) and 3-methylcholanthrene (3-MC: $2 \times 40 \text{ mg/kg}$), the classical inducers of those enzymes. The biochemical modifications were correlated with the altered ability of liver homogenates (S-9 fraction) from similarly pretreated rats to activate benzo(a)pyrene (BP) to intermediates mutagenic in *Salmonella typhimurium*. Styrene or 3-MC administration decreased the K_m of BP hydroxylase and aldrin epoxidase; styrene, but not 3-MC, decreased the K_m of styrene oxide hydratase. Neither of the two compounds modified the K_m of styrene epoxidase. Pretreatment of the rats with styrene or 3-MC enhanced the S-9-mediated mutagenicity of BP sevenfold, compared with the mutagenic response mediated by S-9 preparations from control rats. PB and EB did not modify the K_m of the liver enzymes or the liver-mediated mutagenicity of BP. (32 refs)

- 79-5610** Chromosomal Aberrations Induced by Maleic Hydrazide and Related Compounds in Chinese

Hamster Cells In Vitro. (Eng) Nishi, Y. (Section Cell Biology and Cytogenetics, Biological Res. Center, Japan Tobacco and Salt Public Corp., Hatano, Kanagawa 257, Japan); Mori, M.; Inui, N. *Mutat Res* 67(3): 249-257; 1979.

The cytotoxic effects and chromosome aberrations induced by maleic hydrazide (MH) and related compounds were investigated in cultured Chinese hamster (V79) cells. MH was 5-14 times more cytotoxic than potassium MH (K-MH) and diethanolamine MH (DEA-MH) and almost 4.5 times less toxic than hydrazine dihydrochloride (HDC). When the V79 cells were exposed to these compounds for 3 hr, the LD₅₀ values were (in µg/ml) 1,100 (MH), 12,000 (DEA-MH), 20,000 (K-MH), 230 (HDC), and 10,000 (NaCl). MH, K-MH, and DEA-MH, but not HDC or NaCl, caused chromosome aberrations in cultured V79 cells. The max frequencies of aberrant cells in cultures exposed to the compounds for 3 hr were 18% (MH at 1,000 µg/ml), 18% (K-MH at 20,000 µg/ml), and 13% (DEA-MH at 20,000 µg/ml). Max frequencies observed in cultures treated with HDC or NaCl were 10% (HDC at 400 µg/ml) and 5% (NaCl at 10,000 µg/ml). Max frequencies in positive controls were 97% (N-methyl-N'-nitro-N-nitrosoguanidine at 5 µg/ml) and 16% (ethyl methanesulfonate at 400 µg/ml). The frequencies with MH, K-MH, and DEA-MH were 3.25-4.5 times those in untreated control cells. These results suggest that MH, K-MH, and DEA-MH have weak cytotoxicity and positive cytogenetic effects in V79 cells in vitro. (30 refs)

79-5611 Cytogenetic Action of the Antihypertensive Agent Adelphane on Meiotic Cells of *Poecilocus pictus*. (Eng) Jameela (Cytogenetics Lab., Dept. Genetics, Osmania Univ., Hyderabad 500007, India); Subramanyam, S. *Mutat Res* 67(3): 295-299; 1979.

The cytogenetic action of the antihypertensive agent, Adelphane, on the meiotic cells of the Acridid grasshopper, *Poecilocus pictus*, was studied. The drug (0.0014, 0.0053, or 0.0074 mg) was injected between the third and fourth abdominal segments. Gaps, particularly of the chromatid type, and laggards were the only aberrations seen during spermatogonial division. Gaps, breaks, fragments, and translocations were seen during the meiotic division I stages; and numerical anomalies were seen in diplotene, diakinesis, and metaphase I. Lagging of chromosomes or their fragments was seen at all periods and doses. The mitoclastic effects of Adelphane were seen in cells in the second meiotic division, laggards and groupings being the direct results of such action. Stickiness was observed in all periods. Abnormalities in all divisions were most often seen 24 hr after drug administration, and there was generally a reduction in the frequency of aberrant cells from 24 to 72 hr. It is concluded that the effects induced by Adelphane and/or its metabolites are only transitory. (19 refs)

79-5612 Carcinoma of the Renal Pelvis Following the Abuse of Phenacetin-containing Analgesic Drugs. (Eng) Gaakeer, H. A. (Dept. Urology, City Hosp., Dordrecht, Netherlands); De Ruiter, H. J. *Br J Urol* 51(3): 188-192; 1979.

The occurrence of transitional cell carcinoma of the renal pelvis in five women aged 39-73 yr who had taken approx 5-15 kg of phenacetin over a period of 10 yr is reported. Three of the patients had stopped taking the drug before carcinoma was diagnosed: preexisting nephropathy was not an absolute requirement for the subsequent development of a renal pelvic tumor. It is important to

be aware that a urothelial tumor may develop in patients who abuse phenacetin-containing analgesic drugs and that urine cytology in such cases should be performed at regular intervals. If a malignant tumor of the pelvis is suspected, excretion and retrograde pyelography and urine cytology should be sufficient to establish the diagnosis. (25 refs)

79-5613 Recombinogenicity and Mutagenicity of Saccharin in *Saccharomyces cerevisiae*. (Eng) Moore, C. W. (Dept. Biology, Univ. Rochester, Rochester, NY); Schmick, A. *Mutat Res* 67(3): 215-219; 1979.

Diploid yeast (*Saccharomyces cerevisiae*) grown in the presence of a commercial lot of saccharin exhibited reproducible, dose-dependent increases in intergenic and intragenic recombination and mutation. Cells grew to nearly the same titer in media without saccharin and media containing 2 or 20 mg saccharin/ml, although cell viability was somewhat reduced in saccharin-containing media. At the high test dose of 100 mg/ml, titers and cell viability were more markedly lowered. Differences between this study and previous (negative) tests of saccharin in yeast are described. (20 refs)

79-5614 Glass Capillary Gas Chromatographic Detection and Mass Spectral Analysis of Some Hydroxyl Derivatives of Polychlorinated Biphenyls (PCB's). (Eng) Lotjonen, S. (Dept. Pharmaceutical Chemistry, Univ. Kuopio, P.O. Box 138, SF-70101 Kuopio, Finland); Ayras, P.; Pyysalo, H. *Finn Chem Lett* (2): 57-60; 1979.

Glass capillary gas-liquid chromatographic (GLC) properties and mass spectra of a number of chlorinated biphenyls are reported. Experimental conditions permitting simultaneous detection of polychlorinated biphenyls and their hydroxylated derivatives by GLC and identification of the latter compounds by mass spectrometry are described. (16 refs)

79-5615 Metabolism of Benzidine to N-Hydroxy-N,N'-diacetylbenzidine and Subsequent Nucleic Acid Binding and Mutagenicity. (Eng) Morton, K. C. (Michigan Cancer Foundation, 110 E. Warren Ave., Detroit, MI 48201); King, C. M.; Baetcke, K. P. *Cancer Res* 39(8): 3107-3113; 1979.

Benzidine (BZ) metabolism was shown to include the following sequence: BZ → N-acetylbenzidine (ABD) → N,N'-diacetylbenzidine (DABZ) → N-hydroxy-N,N'-diacetylbenzidine → nucleic acid binding. BZ was acetylated in a two-step, acetylcoenzyme A-dependent reaction catalyzed by liver cytosol from hamsters, guinea pigs, mice, and rats (listed in order of decreasing enzyme activity). ABZ and DABZ were identified by thin-layer and high-pressure liquid chromatography and by mass spectrometry. The first acetylation step was more rapid than the second in all species except the guinea pig, in which the rates were equal. ¹⁴C-DABZ was hydroxylated by fortified liver microsomes (hamster > mouse > rat) to yield both N-hydroxy- and 3-hydroxy-¹⁴C-DABZ, which were identified by isotope dilution and/or mass spectrometry. Isotope dilution experiments did not detect the formation of ¹⁴C-N-acetyl-N'-glycolyl-BZ during these incubations. Pretreatment of animals with 3-methylcholanthrene enhanced N- and 3-

hydroxylation in all cases except for 3-hydroxylation by hamsters. Chemically synthesized ^{14}C -N-hydroxy-N-acetyl-N'-acetyl-BZ bound to transfer RNA in the presence of liver cytosol. The binding was catalyzed by an N,O-acyltransferase that varied in the order hamster > rat > mouse. N-Hydroxy-DABZ was mutagenic for *Salmonella typhimurium* TA1538 in the presence of a partially purified N,O-acyltransferase preparation. These data suggest that BZ can be metabolized to reactive derivatives that may contribute to the induction of tumors. (55 refs)

- 79-5616 The In Vitro Binding of 2,2',5,5'-Tetrachlorobiphenyl Metabolites to Rat Liver Microsomal Proteins. (Eng) Hargraves, W. A. (Dept. Pathology, Medical Sch., Univ. Wisconsin, Madison, WI 53706); Allen, J. R. *Res Commun Chem Pathol Pharmacol* 25(1): 33-52;

The in vitro association of ^3H -labeled 2,2',5,5'-tetrachlorobiphenyl (TCB) with the microsomal fraction isolated from rat livers was investigated in a metabolizing system that allows the nature of the binding of the TCB metabolite(s) to the microsomal proteins to be characterized. Control microsomes, capable of only minimal TCB metabolism, had 92% of their total radioactivity associated with membrane lipids, but only 61% of the radioactivity of the phenobarbital-induced microsomes was lipid-bound. The radioactivity per milligram of microsomal protein was the same for both induced and noninduced microsomes; however, very important qualitative differences were found. Only the proteins of the induced system contained a protein(s) (mol wt = 45,000 g/mol) capable of specifically binding a TCB metabolite. This binding required metabolism and was TCB-concentration dependent. The specificity of this association was confirmed by dialysis, and the data could be analyzed by the Scatchard-Klotz equation. These calculations allowed evaluation of the number of binding sites (38 micromoles/g total microsomal protein) and the apparent binding constant (1.4×10^7 liters/mole). These data are consistent with a strong noncovalent interaction of a 2,2',5,5'-TCB metabolite, but they do not exclude the possibility of covalent binding of other nondialyzable metabolites. (44 refs)

- 79-5617 Mechanisms of Action of Carcinogenic Aromatic Amines: An Investigation Using Mutagenesis in Bacteria. (Eng) Scribner, J. D. (Pacific Northwest Res. Foundation, 1102 Columbia St., Seattle, WA 98104); Fisk, S. R.; Scribner, N. K. *Chem Biol Interact* 26(1): 11-25; 1979.

The mutagenicities of several N-acetoxy-N-arylamines, nitroarenes, arylamides, and arylamines were determined in *Salmonella typhimurium* tester strains TA98, TA1538, TA100, TA1535, and TA1537. Three broad classes of mutagenic activity were found: class A, including 2-naphthylamine, produced essentially only base-pair substitution without induction of error-prone repair; class B, including 4-aminobiphenyl, caused considerable induction of error-prone repair, accompanied by a lower level of frame-shifting; class C, including N-acetoxy-2-acetamidofluorene, produced high levels of frame-shifting, with some induction of error-prone repair. Correlation of these results with known reactions of certain aromatic amine derivatives with nucleosides and nucleic acids, and with molecular orbital calculations, suggests that the class A effect is produced by small aromatic groups attached to extranuclear heteroatoms in DNA bases, the class B effect is caused by large aromatic groups attached to extranuclear heteroatoms or by arylamines attached to the C-8 of guanine, and

the class C effect is caused by arylamides attached to the C-8 of guanine, probably rotating into the helix. The data also suggest that the N-acetoxy-N-arylamines are generally useful models for ultimate metabolites derived in vivo, even if the in vivo metabolites do not carry an acetyl group. There was a rough correlation between the sum of the reversions induced in TA98 and TA100 by the N-acetoxy-N-arylamines and their previously determined local carcinogenicities. There was a poor correlation between mutagenicity in any one tester strain and carcinogenicity. (33 refs)

- 79-5618 The Microsomal Activation of Aflatoxin B₁ and 2-(N-Ethylcarbamoyloxymethyl) furan In Vitro Using a Novel Diffusion Apparatus. (Eng) Neal, G. E. (MRC Toxicology Unit, Medical Res. Council Labs., Woodmansterne Road, Carshalton, Surrey SM5 4EF, England); Mattocks, A. R.; Judah, D. J. *Biochim Biophys Acta* 585(1): 134-142; 1979.

The in vitro activation of aflatoxin B₁ (AFB) and 2-(N-ethylcarbamoyloxymethyl) furan (CMF) by liver microsomes from phenobarbital-pretreated adult male Fischer rats was studied. Max binding of DNA was reached at approx 250 nanomoles of AFB and CMF, but the level of binding was 200 picomoles (pmol) of CMF vs 3,000 pmol of AFB per micromole of DNA. The binding of the active microsomal metabolite of CMF to protein was inhibited by GSH, whereas GSH increased the level of binding of CMF to DNA. GSH had no effect on the binding of AFB to protein or DNA. The active metabolite of CMF was able to bind covalently to DNA separated by a membrane barrier from the microsomal site of activation. In the case of AFB, the DNA had to be in physical contact with the microsomal system for its active metabolite to bind covalently. The results suggest that the subcellular site of activation of AFB, unlike that of CMF, may need to be adjacent to the target DNA. This site might be the outer nuclear membrane, or a carrier molecule might exist for the activated AFB metabolite in vivo. (15 refs)

- 79-5619 Histopathology, Autoradiography and Microphotometry of the Rat Liver After Feeding with Aflatoxin B₁. (Eng) Arora, H. L. (Dept. Histopathology, St. George's Hosp. Medical Sch., Tooting, London, England); Butler, W. H. *Indian J Cancer* 15(3): 8-13; 1978.

Sequential changes in the livers of male albino Fischer rats fed 5 ppm aflatoxin B₁ (AFB) for 1-6 wk were studied. After 1 wk of AFB feeding, the architecture of the liver lobule was preserved, but there were areas of focal and individual cell necrosis. After 3 wk, periportal necrosis, extensive proliferation of oval cells, variations in the size of the remaining parenchymal cells, and their nuclei, and increased numbers of mitotic figures were prominent features. After 4.5 wk, focal areas of liver cell necrosis were distributed throughout the liver lobule. The proliferating hyperplastic nodules were of two types: one consisted of small cells having a deeply stained cytoplasm with uniform-sized nuclei and one consisted of larger cells with a vacuolated cytoplasm and bizarre nuclei. These two types of nodules were present in enhanced size and number at 6 wk. The percentage of parenchymal cells labeled with ^3H -thymidine did not differ significantly in control and AFB-fed rats, but the percentage of labeled cells was significantly increased in the hyperplastic nodules compared with that in other parts of the liver. There was increased microphotometric absorptivity of DNA in the periportal area after 6 wk of AFB feeding. DNA absorbance was lower in the small cell nodules than in the large cell nodules. (19 refs)

- 79-5620 Comparison of Aflatoxin B₁ and Aflatoxin G₁ Binding to Cellular Macromolecules In Vitro, In Vivo and after Peracid Oxidation; Characterisation of the Major Nucleic Acid Adducts. (Eng) Garner, R. C. (Cancer Res. Unit, Univ. York, Heslington, York YO1 5DD, England); Martin, C. N.; Smith, J. R.; Coles, B. F.; Tolson, M. R. *Chem Biol Interact* 26(1): 57-73; 1979.

The binding of [¹⁴C]aflatoxin B₁ (AFB₁) and [¹⁴C]aflatoxin G₁ (AFG₁) to rat liver and kidney cellular macromolecules was compared. The percentage uptake of [¹⁴C]AFG₁ or [¹⁴C]AFB₁ by the liver and kidney after ip administration to Wistar rats (60 µg/100 g) was not significantly different for the two mycotoxins. Max uptake occurred at 2 hr. However, the amount of binding with liver DNA, ribosomal RNA, and protein was different. The greatest difference was found in the amount of binding with ribosomal RNA, which was significantly less for AFG₁. AFG₁ binding to DNA also tended to be lower, but this was significant only at 2 and 24 hr. Protein binding was not significantly different for the two mycotoxins. As reported previously for AFB₁, there was more binding of AFG₁ to nucleic acids than to protein. The loss of radioactivity from liver DNA or ribosomal RNA for both [¹⁴C]AFB₁ and [¹⁴C]AFG₁ appeared to be biphasic, indicating that an enzymic DNA repair process may be operating. In the kidney, AFB₁ appeared to bind more to DNA and protein than AFG₁. Insufficient ribosomal RNA was recovered for accurate determination of binding. In vitro binding studies also showed that less AFG₁ was bound to exogenous DNA after microsomal activation than AFB₁. This difference was not a result of differences in the chemical reactivity of the ultimate electrophilic species, the respective epoxides, since chemical activation studies using 3-chloroperbenzoic acid showed that similar amounts of AFG₁ and AFB₁ were converted to the epoxides and were bound to DNA. According to the distribution coefficients of the two mycotoxins, AFB₁ was more lipophilic than AFG₁, a factor that may be important in determining the weaker carcinogenicity of the latter. Characterization of the major AFG₁-DNA adduct formed in vitro, in vivo, and after peracid oxidation showed it to have the structure trans-9,10-dihydro-9-(7-guanyl)-10-hydroxyafatoxin G₁. This adduct is similar to that obtained from AFB₁ by activation in vivo, in vitro, and after peracid oxidation. (33 refs)

- 79-5621 Sensitivity of Cultured Rat Hepatocytes to Aflatoxin B₁ and Benzo(a)pyrene. (Eng) Schaeffer, W. I. (Dept. Medical Microbiology, Univ. Vermont Coll. Medicine, Given Medical Building, Burlington, VT 05405); Chuang, A. H.; Heintz, N.; Bresnick, E. *In Vitro* 15(6): 437-440; 1979.

The sensitivity of a cloned rat hepatocyte line, RL-PR-C, to aflatoxin B₁ (50 µg/ml) and benzo(a)pyrene (10 µg/ml) was tested as a function of population-doubling level. The cells were much more sensitive to the cytotoxic action of these agents subsequent to 230 population doublings. This sensitivity corresponded to the enhanced inducibility of aryl hydrocarbon hydroxylase activity by 3-methylcholanthrene. (9 refs)

- 79-5622 Biologically Active Phorbol Esters Specifically Alter Affinity of Epidermal Growth Factor Membrane Receptors. (Eng) Shoyab, M. (Lab. Viral Carcinogenesis, NCI, NIH, Bethesda, MD 20205); De Larco, J. E.; Todaro, G. J. *Nature* 279(5712): 387-391; 1979.

The effects of 12-O-tetradecanoylphorbol-13-acetate (TPA) and

related tumor promoters on the interactions between epidermal growth factor and its membrane receptors were investigated. TPA reversibly inhibited the binding of ¹²⁵I-labeled EGF to treated mouse and human cells, but it did not affect the binding of various other ligands to their membrane receptors. It altered the affinity of the receptors for EGF without changing the total number of available receptors per cell. Phorbol esters that stimulate cell growth in culture and have tumor-promoting activity in vivo altered the EGF-receptor affinity, but the biologically inactive derivatives failed to change the affinity of EGF for its receptors. (30 refs)

- 79-5623 Inhibition of Phorbol Ester-accelerated Amino Acid Transport in Bovine Lymphocytes. (Eng) Kensler, T. W. (McArdle Lab. Cancer Res., Univ. Wisconsin, Madison, WI 53706); Wertz, P. W.; Mueller, G. C. *Biochim Biophys Acta* 585(1): 43-52; 1979.

The ability of 12-O-tetradecanoylphorbol-13-acetate (TPA) to modulate the uptake of α-aminoisobutyric acid (AIA) by bovine lymphocytes was studied. TPA effectively stimulated AIA uptake over a 5-hr test period following a 20-min lag period. The response was max with 1-10 nanomolar (nM) TPA. At 0.1 nM, TPA was without effect, and at higher concentrations, eg, 1 mM, TPA diminished this response, presumably due to toxic effects. In general, a good correlation existed between the tumor-promoting activities of a variety of phorbol esters tested and their capacity to rapidly accelerate AIA uptake by bovine lymphocytes. Actinomycin D and cycloheximide, but not cytochalasin B or colchicine, partially antagonized the TPA-stimulated uptake of AIA. This uptake was significantly antagonized by retinoic acid, but the epoxy derivatives of retinoic acid and structurally related analogs were inactive as antagonists. Ouabain antagonized TPA-stimulated uptake only slightly. Comparative studies in lymphocytes showed that TPA elicits a number of metabolic responses that appear to originate at the cell membrane and that these responses are differentially antagonized by retinoic acid, the 5,6-epoxide of retinoic acid, and related retinoid analogs. (22 refs)

- 79-5624 Melittin Shares Certain Cellular Effects with Phorbol Ester Tumour Promoters. (Eng) Mufson, R. A. (Div. Environmental Sciences, Inst. Cancer Res., Columbia Univ., Coll. Physicians and Surgeons, 701 W. 168th St., New York, NY 10032); Laskin, J. D.; Fisher, P. B.; Weinstein, I. B. *Nature* 280(5717): 72-74; 1979.

Melittin (ME), a 26-amino acid polypeptide of known sequence, is a major component of bee venom. Because of its amphipathic character, it can be inserted into phospholipid bilayers and it exhibits surfactant activity. When ME (8 × 10⁻⁷ M) or 12-O-tetradecanoylphorbol-13-acetate (TPA: 2 × 10⁻⁸ M), another amphipathic but structurally unrelated compound, was added to cultures of normal C3H/10T1/2 mouse embryo fibroblasts, there was a two- to threefold enhancement of arachidonic acid and prostaglandin E₂ release 3 hr later. When ME (8 × 10⁻⁷ M) or TPA (1 × 10⁻⁷ M) was added to cultures of C3B16 mouse melanoma cells shortly after plating, there was a 24-hr delay in the onset of melanogenesis and a 66% inhibition of pigment formation. This delay in differentiation was not due to growth inhibition or cytotoxicity, as assayed by cell growth rate, time required to reach confluence, or cell DNA content. When ME (8 × 10⁻⁷ M) or TPA (2 × 10⁻⁸ M) were added to adenovirus-transformed rat embryo cells in soft agar culture to assay anchorage-independent growth, there

was an approx threefold increase in cloning efficiency compared with that of control cultures. ME should be useful for examining whether the pleiotropic effects of phorbol ester tumor promoters are secondary to their membrane effects or whether certain effects are mediated by non-membrane-related events. It will also be of interest to determine whether ME itself has tumor-promoting activity. (20 refs)

- 79-5625** A Tumor-promoting Phorbol Ester Inhibits the Cyclic AMP Response of Rat Embryo Fibroblasts to Catecholamines and Prostaglandin E₁. (Eng) Rochette-Egly, C. (Institut de Recherches Scientifiques sur le Cancer, Boite Postale no. 8, 94 800 Villejuif, France); Castagna, M. *FEBS Lett* 103(1): 38-42; 1979.

The cyclic AMP response of cultured rat embryo fibroblasts to prostaglandin E₁, L-epinephrine, and L-phenylephrine was inhibited by pretreatment with 12-O-tetradecanoylphorbol-13-acetate (TPA, 100 ng/ml). However, there was no evidence for a TPA-mediated linkage of adenylate cyclase to α -adrenergic receptor. (26 refs)

- 79-5626** Tumour Promoter TPA Enhances Transformation of Human Leukocytes by Epstein-Barr Virus. (Eng) Yamamoto, N. (Institut fur Virologie, Zentrum fur Hygiene, Universitat Freiburg, Herman-Herder-Strasse 11, 78 Freiburg, W. Germany); zur Hausen, H. *Nature* 280(5719): 244-245; 1979.

The effects of 12-O-tetradecanoylphorbol-13-acetate (TPA) on virus induction in Epstein-Barr virus (EBV) genome-harboring cells and on the EBV-induced transformation of human cord blood lymphocytes were analyzed. In the presence of TPA, cord blood WBC infected by EBV showed a sixfold enhancement in the number of transformed colonies and increased colony size, compared with infected cultures grown without TPA. The optimal TPA concentration was 0.31 nanogram/ml and the max number of colonies was obtained at a virus dilution of 1:4. No transformed lymphoblastoid colonies were observed in cultures treated exclusively with TPA. TPA did not enhance colony formation in one EBV genome-negative cell line or in three EBV-positive lines, although it increased colony formation in a fourth EBV-positive line approx threefold. TPA also increased transformation efficiency in liquid culture systems. The results suggest that TPA acts on transformation steps rather than inducing nonspecific colony-stimulating factors known to promote cell growth in agarose. (20 refs)

- 79-5627** The Surface Structure of 7,12-Dimethylbenz(a)anthracene Transformed C3H/10T1/2 Cells. A Quantitative Scanning Electron Microscopical Study. (Eng) Saxholm, H. J. (Inst. Pathology, Univ. Oslo, Rikshospitalet, Oslo 1, Norway); Reith, A. *Eur J Cancer* 15(6): 843-855; 1979.

The relationship between the oncogenicity of 7,12-dimethylbenz(a)anthracene (DMBA)-transformed mouse embryo (C3H/10T1/2) cells and their surface concentration of long microvilli was studied. The cells developed three types of morphologically altered foci after exposure to DMBA. The types II and III cells showed oncogenic potential, whereas the type I cells remained nononcogenic. Scanning electron microscopy showed that the concentration of

short microvilli increased with increasing cell culture passage for all three types. Only on types II and III cells were long microvilli observed. There was a significant correlation between the oncogenic potential and the presence of long microvilli. This observation may be of value in screening for oncogenic transformation of cells in culture. (15 refs)

- 79-5628** Apurinic Acid Endonuclease Activity from Mouse Epidermal Cells. (Eng) Ludwig, G. (Deutsches Krebsforschungszentrum, Institut fur Biochemie, Im Neuenheimer Feld 280, 6900 Heidelberg, W. Germany); Thielmann, H. W. *Nucleic Acids Res* 6(8): 2901-2917; 1979.

An endonuclease activity causing single-strand scissions in depurinated and alkylated viral (PM2) DNA was purified 500-fold from perinatal mouse skin epidermal cells transformed in vitro by 7,12-dimethylbenz(a)anthracene. The enzyme was active only at apurinic/aprimidinic sites, regardless of whether these were produced by heating the DNA at an acidic pH or by alkylation with the ultimate carcinogen MeSO₂OMe. The enzyme was inactive on native DNA, on UV-induced pyrimidine dimers in DNA, and on steric distortions (N-2-fluorenylacetyl residues) by modification of the DNA with the carcinogen (Ac)₂ONFln. The purified enzyme fraction was shown to be free of exonuclease, demethylase, and DNA glycosylase activities specific for bases methylated with MeSO₂OMe or MeNOUr. The enzyme was active in the presence of 1 mM EDTA, but its activity was stimulated threefold by the presence of 3-10 mM MgCl₂. Raising the KCl concentration from 40 to 120 mM in a 5 mM Tris-HCl buffer (pH 7.4) resulted in optimum enzyme activity, but KCl concentrations in excess of 200 mM were completely inhibitory. Optimum activity also occurred in 10-40 mM potassium phosphate buffer (pH 7.4). The enzyme did not bind to diethylaminoethylcellulose, but it was eluted from hydroxyapatite, phosphocellulose, and heparin-cellulose columns by 100-250 mM potassium phosphate. The diffusion constant of the enzyme was determined to be 8.2×10^{-7} cm²/sec, the sedimentation coefficient in linear sucrose gradients approx 2.7S, the mol wt approx 31,000 daltons, and the axial ratio approx 4:1. (40 refs)

- 79-5629** A Comparison of the Capacity of Fetal and Adult Liver, Lung, and Brain to Convert Polycyclic Aromatic Hydrocarbons to Mutagenic and Cytotoxic Metabolites in Mice and Rats. (Eng) Juchau, M. R. (Dept. Pharmacology, Univ. Washington, Sch. Medicine, Seattle, WA 98195); DiGiovanni, J.; Namkung, M. J.; Jones, A. H. *Toxicol Appl Pharmacol* 49(1): 171-178; 1979.

Preparations of S-9 fractions from the fetal brains of rats displayed a high capacity to convert 7,12-dimethylbenz(a)anthracene to metabolites mutagenic to *Salmonella typhimurium* tester strains TA-98, TA-100, and TA-1538. The same tissue was only minimally active or inactive in converting benzo(a)pyrene or N-2-fluorenylacetylacetamide to mutagenic metabolites. Fetal brain tissues of mice were virtually inactive with respect to the bioactivation of each of the three procarcinogens but fetal pulmonary tissues of mice produced mutagen-generating activities that were five- to ninefold above background with respect to 7,12-dimethylbenz(a)anthracene. Fetal hepatic and brain tissues of mice also catalyzed the conversion of each of the three promutagens to cytotoxic intermediates, but this phenomenon was not observed with fetal hepatic or brain tissues of rats. Analysis with high-pressure liquid chromatography demonstrated that brain tissues of fetal mice were very active in converting 7,12-dimethylbenz(a)anthracene to ox-

xygenated metabolites, whereas the fetal brain tissues of rats were only minimally active. The chromatographic patterns observed also indicated that different metabolites were formed in the presence of S-9 fractions from rats vs mice. The data are consistent with the hypothesis that the previously observed species difference in susceptibility to transplacental tumorigenesis by polycyclic hydrocarbons is related to differences in target organ biotransformation of these compounds. - 79-5630 Transplantation of Hamster Buccal Pouch Carcinoma to Neonatal Hamsters. (Eng) Merk, L. P. (Dept. Oral Medicine and Oral Pathology, Harvard Sch. Dental Medicine, 188 Longwood Ave., Boston, MA 02115); Shklar, G.; Albright, J. *Oral Surg* 47(6): 533-538; 1979.

The transplantation of 9,10-dimethyl-1,2-benzanthracene-induced Syrian hamster buccal pouch epidermoid carcinomas into syngeneic neonatal hamsters by sc and ip inoculation was studied. All recipients and littermate controls were given rabbit anti-hamster lymphocyte serum (ALS) at the time of tumor injection and thrice weekly thereafter. The controls given ALS showed no evidence of tumor growth or other pathology. The sc transplanted tumors ulcerated within a week and sloughed off, leaving a scar. The ip transplanted tumors grew rapidly in all four animals, involving the pancreas and areas around the spleen and intestines. The degree of organ infiltration was greater at 31 days than at 15 or 21 days. The abdominal tumors were epidermoid carcinomas that were significantly more anaplastic than the original buccal pouch tumors. They were characterized by extensive necrosis and cellular proliferation, with notable pleomorphism and hyperchromatism and an altered nuclear:cytoplasmic ratio. (13 refs)

- 79-5631 Metabolism of 7,12-Dimethylbenz(a)anthracene and Its Methyl-hydroxylated Metabolites: Formation of Phenolic Metabolites at the 2-Positions. (Eng) Chou, M. W. (Dept. Pharmacology, Sch. Medicine, Uniformed Services Univ. Health Sciences, Bethesda, MD 20014); Easton, G. D.; Yang, S. K. *Biochem Biophys Res Commun* 88(3): 1085-1091; 1979.

Four 2-phenols were identified as rat liver microsome metabolites of 7,12-dimethylbenz(a)anthracene (DMBA) and its methyl-hydroxylated metabolites 7-hydroxymethyl-12-methylbenz(a)anthracene, 7-methyl-12-hydroxymethylbenz(a)anthracene, and 7,12-dihydroxymethylbenz(a)anthracene. The phenols were identified by their UV-visible absorption and fluorescence spectra and their high-pressure liquid chromatography retention times and by mass spectral analyses. The findings suggest that the presence of the 12-methyl group or the 12-hydroxymethyl group suppresses rather than blocks the microsomal oxygenations at the 1,2 positions of DMBA or its methyl-hydroxylated derivatives. The 2-phenols may be formed as nonenzymatic rearrangement products of the 1,2-epoxide intermediates, although their formation by a direct hydroxylation mechanism cannot be ruled out. (15 refs)

- 79-5632 Changes in Mouse Skin Cyclic Nucleotides During Chemical Carcinogenesis and Tumor Response to Treatment with BCG, L-Dopa and Cyclic DBAMP. (Eng) Busse, E. (Oncological Clinic, Medical Sch., Humboldt-Universitat Berlin, Schumannstrasse 20/21, DDR-1040 Berlin, E. Germany); Rose, H.; Riessbeck, K. H. *J Cancer Res Clin Oncol* 94(2): 121-130; 1979.

Changes in mouse skin cyclic nucleotides were studied in male ICR mice treated with topical 9,10-dimethyl-1,2-benzanthracene (DMBA) and subsequently with BCG, L-dopa, and/or dibutyryl cyclic AMP (dbAMP). Papillomas appeared on all DMBA-treated animals within 35-49 days and skin tumors appeared on 73/80 within 105 days. Up to 24 hr after the first application of DMBA, both cAMP and guanosine monophosphate (GMP) levels rose. Later, the cAMP level fell below that of normal tissue. The tumors continued to grow deeper into the tissue and increase in size in 15/15 untreated animals, 14/18 animals treated with BCG, 8/20 animals treated with L-dopa + dbAMP, and 4/20 animals treated with L-dopa, dbAMP, and BCG. The neoplastic growths reached a stationary phase in 4/18 mice given BCG, 7/20 mice given L-dopa + dbAMP, and 5/20 mice given L-dopa, dbAMP, and BCG. Tumor regression was observed in 5/20 animals given L-dopa + dbAMP and 11/20 mice given L-dopa, dbAMP, and BCG. cAMP and GMP levels in the skin of mice that had undergone tumor regression were similar to those in normal animals, whereas the levels in mice that did not respond to treatment were similar to those in untreated animals. In mice given Ehrlich ascites tumor cells im, solid tumors with lowered cAMP:cGMP ratios developed. No tumors developed in 6/30 mice treated with L-dopa, dbAMP, and BCG at the time of tumor inoculation or in 20/30 mice treated similarly prior to tumor inoculation. (27 refs)

- 79-5633 Inhibition of Phorbol Ester-induced Tumor Promotion in Mice by Vitamin A Analog and Anti-inflammatory Steroid. (Eng) Weeks, C. E. (Biology Div., Oak Ridge Natl. Lab., P.O. Box Y, Oak Ridge, TN 37830); Slaga, T. J.; Hennings, H.; Gleason, G. L.; Bracken, W. M. *J Natl Cancer Inst* 63(2): 401-406; 1979.

The chemopreventive potential of a vitamin A analog, TMMP ethyl retinoate [ethyl-9-(4-methoxy-2,3,6-trimethylphenyl)-3,7-dimethyl- trans-2,4,6,8- nonatetraenoate; Ro 10-9359], and/or an anti-inflammatory steroid, fluocinolone acetonide [6 α ,9 α -difluoro-11 β ,16 α ,17,21-tetrahydroxypregna-1,4-diene-3,20-dione cyclic 16,17-acetal; FA], was studied in a two-stage carcinogenesis system. The phorbol ester 12-O-tetradecanoylphorbol-13-acetate (TPA) was used as the tumor promoter in a 7,12-dimethylbenz(a)-anthracene (DMBA)-initiated mouse skin system. Two stocks of female mice, CD-1 and Sencar, which differ in their degrees of sensitivity to skin carcinogenesis, were used. A dose-dependent inhibition of carcinogenic expression, as determined by a decreased number of papillomas per animal, was observed in each mouse stock with the use of FA or Ro 10-9359 alone. When FA and Ro 10-9359 were given together, the decrease in tumor incidence was enhanced. FA effectively inhibited tumor formation in the sensitive mouse stock, even when the steroid was given 1 day prior to TPA treatment under conditions of unusually high doses of initiator (DMBA) and/or promoter (TPA). These results suggest that both anti-inflammatory steroids and retinoids inhibit tumor promotion and can be effectively used as a combination regimen for an increased chemopreventive response. (49 refs)

- 79-5634 Tumorigenicity of the Diastereomeric Benz(a)anthracene 3,4-diol-1,2-epoxides and the (+) and (-) Enantiomers of Benz(a)anthracene 3,4-Dihydrodiol in Newborn Mice. (Eng) Wislocki, P. G. (Merck, Sharp & Dohme Res. Labs., Rahway, NJ 07065); Buening, M. K.; Levin, W.; Lehr, R. E.; Thakker, D. R.; Jerina, D. M.; Conney, A. H. *J Natl Cancer Inst* 63(1): 201-204; 1979.

The tumorigenicity of benz(a)anthracene (BA), the (+)- and (-)-enantiomers of trans-3,4-dihydroxy-3,4-dihydrobenz(a)anthracene (BA 3,4-dihydrodiol), and the racemic diastereomers of the BA 3,4-diol-1,2-epoxides [ie, either or both of the diastereomeric 1,2-epoxides derived from BA 3,4-dihydrodiol in which the epoxide oxygen is cis (diol epoxide-1) or trans (diol epoxide-2) to the benzylic 4-hydroxyl group] was examined in newborn Swiss-Webster mice. The mice were inoculated ip with 280 nanomoles (nmol) of one of the test compounds in divided doses: 40 nmol within 24 hr of birth, 80 nmol at 8 days of age, and 160 nmol at 15 days of age. The experiment was terminated when the animals were 26 wk old. Diol-epoxide-2 was the most potent compound tested. All animals treated with diol-epoxide-2 developed pulmonary tumors, with an av of 13.3 tumors per mouse. Diol-epoxide-1 produced pulmonary tumors in 42% of the mice with an average of only 0.56 tumor per mouse. The (-)-enantiomer of BA 3,4-dihydrodiol with [3R,4R] absolute stereochemistry was the second most tumorigenic derivative of BA tested; it produced pulmonary tumors in 71% of the mice with an av of 1.88 tumors per mouse. BA and the (+)-enantiomer of BA 3,4-dihydrodiol had little or no tumorigenicity at the dose tested. A comparison of the av number of pulmonary tumors per mouse revealed that diol-epoxide-2 was about 30-fold more tumorigenic than diol-epoxide-1, 8-fold more tumorigenic than (-)-BA 3,4-dihydrodiol, and >85-fold more tumorigenic than BA. These data indicate that in newborn mice, BA 3,4-dihydrodiol and a BA 3,4-diol-1,2-epoxide are proximate and ultimate carcinogenic metabolites of BA, respectively. (22 refs)

79-5635 Distribution of ^3H -7,12-Dimethylbenz(a)anthracene in the Rat Neuroendocrine System. (Rus) Anisimov, V. N. (Lab. Endocrinology, N. N. Petrov Res. Inst. Oncology, Leningrad, USSR); Aleksandrov, V. A. *Vopr Onkol* 25(6): 84-88; 1979.

The effects of the neuroendocrine system on the carcinogenicity of polycyclic aromatic hydrocarbons was evaluated. Random-bred rats were inoculated iv with a mixture of unlabeled 7,12-dimethylbenz(a)anthracene (DMBA: 15 mg/kg) and ^3H -DMBA (0.05 mCi/kg). Rats were sacrificed 30 min or 3, 6 or 12 hr later, and the distribution of ^3H -DMBA in different tissues and organs was determined. At 30 min postinoculation, there was a max accumulation of label in the liver, and the radioactivity in the endocrine glands was significantly greater than that in muscle tissue. At 3 hr postinoculation, there was a significant accumulation of label in the adrenals. Label accumulation in the mediobasal hypothalamus at 30 min and at 6 and 12 hr postinoculation was significantly greater than that in the cerebral cortex and dorsal hypothalamus. (26 refs)

79-5636 Collagen Synthesis in Capsules Surrounding Dimethylbenzanthracene-induced Rat Breast Tumors and the Effect of Pretreatment with β -Aminopropionitrile. (Eng) Cohen, I. K. (Dept. Surgery, Medical Coll. Virginia, Virginia Commonwealth Univ., Richmond, VA 23298); Moncure, C. W.; Witorsch, R. J.; Diegelmann, R. F. *Cancer Res* 39(8): 2923-2927; 1979.

Collagen and total protein synthesis within the parenchyma and capsule of dimethylbenzanthracene (DMBA)-induced Sprague-Dawley rat breast tumors was compared, and the findings were correlated with tumor histology. In addition, an attempt was made to determine if alterations in the collagenous stroma by inhibition

of collagen cross-linking with β -aminopropionitrile (BAPN) would inhibit capsule formation and allow the tumor to metastasize. Collagen synthesis was increased over threefold in the tumor capsules compared with that in the parenchyma and over sixfold compared with that in normal breast connective tissue. Increased collagen synthesis was independent of the rate of tumor growth and final tumor size. Pretreatment of animals with BAPN caused an 82% decrease in tumor formation and a significant reduction in tumor volume (approx 0.4 cm³) compared with controls (approx 10 cm³). The few small tumors that did develop in the lathyrin animals had increased collagen synthesis in the interior tumor stroma and reduced collagen synthesis in the tumor capsule. These findings suggest that the collagenous capsule surrounding DMBA-induced tumors functions as a physical barrier to protect the tumors from the immune system of the host. The apparent antitumor effects of BAPN may be due to its immunopotential and/or cytotoxic actions. (12 refs)

79-5637 Estradiol Binding to Nuclear Receptors in Human Breast Cancer Tissue (MCF-7 Cell Line) and in Dimethylbenz(a)anthracene-induced Mammary Carcinoma. (Eng) Geier, A. (Inst. Endocrinology, Chaim Sheba Medical Center, Tel-Hashomer, Israel); Cocos, M.; Ginzburg, R.; Haimsohn, M.; Lunenfeld, B. *J Clin Endocrinol Metab* 49(1): 34-39; 1979.

Nuclear estradiol receptors (NR's) were measured in human breast carcinoma tissue (cell line MCF-7) and in dimethylbenz(a)anthracene-induced rat mammary carcinomas by an assay that makes use of the fact that, at low salt concentration, the NR is bound to particles (chromatin) and can be separated from the soluble components that contain proteolytic activity. R degradation by intracellular proteases was avoided by repeated washing of the particulate-bound R. Thus, the amount of occupied NR's (bound by endogenous estrogen) could be measured by exchange at 30 C, and the amount of unoccupied R's could be measured at 4 C. R's were measured by a single saturating dose of 7.5 nanomolar [^3H]estradiol with or without a 100-fold excess of diethylstilbestrol to estimate the amount of nonspecific binding. In mammary tumors from castrated rats, unoccupied R's were found in the cytoplasm. In the nucleus, neither occupied nor unoccupied R's could be detected. Thirty min after injection of estradiol, unoccupied estradiol R's were no longer detected in the cytoplasm. However, 35-50% of the cytoplasmic R's detected in the castrated rats were found as occupied NR's. Before exposure to estradiol, MCF-7 cells contained only unoccupied nuclear and cytoplasmic R's. After a 1-hr exposure to estradiol, only occupied NR's were found. The total amounts of R's before and after treatment were similar. Nuclear and cytoplasmic estradiol R's were measured in 44 human breast tumors. Ten tumors contained neither cytoplasmic nor NR's. In 29/34 patients whose tumors contained cytoplasmic R's, unoccupied NR's were present. Occupied NR's were found in 21/34 of these tumors, in the younger as well as the older patients. However, the latter contained higher levels of cytoplasmic R's. These findings indicate that the presence of occupied NR's in these tumors may depend on various factors, including the circulating levels of estradiol, tumor cytoplasmic R levels, and the translocative ability of the cytoplasmic R. (20 refs)

79-5638 Effect of Microsomal Preparations and Induction on Cytochrome P-450-dependent Monooxygenases in Fetal and Neonatal Rat Liver. (Eng) Cresteil, T. (Laboratoire de Biochimie, CHU Necker-Enfants Malades, 156 rue de Vaugirard, 75730 Paris Cedex 15, France); Flinois, J. P.; Pfister, A.; Leroux, J. P. *Biochem Pharmacol* 28(13): 2057-2063; 1979.

The sedimentation behavior of fetal and neonatal Sprague-Dawley rat liver microsomes was determined with the use of an EDTA-containing buffer, which allowed better recovery of a less-contaminated microsomal fraction. The specific cytochrome P-450 content and related catalytic activities in the 105,000 g pellet of fetal and neonatal liver were thus much higher than those usually reported, but molecular catalytic activities were comparable to those of adults. The transplacental inducing effects of phenobarbital (PB) and 3-methylcholanthrene (3-MC) on the monooxygenase system were studied in microsomes prepared by the modified procedure and compared with results obtained in a crude liver homogenate. 3-MC induced a net biosynthesis of cytochrome P-450 in fetal liver, whereas PB produced only a premature transformation of rough into smooth endoplasmic reticulum, which decreased the contamination of the 105,000 g pellet by ribosomal protein. As a result, the specific cytochrome P-450 level in the microsomal fraction appears to be increased by PB, although there is no true induction of the monooxygenase system in near-term rat fetuses. (40 refs)

- 79-5639 Methylcholanthrene-induced Tumors in Resistant and Sensitive Jensen Sarcoma Rats. I. Effect of Fresh Prepared MC Emulsion. (Eng) Lupu, A. (Oncological Inst. Bucharest, Piata Kogalniceanu 7, ET2, Ap 4, Sector 6, Bucharest, Romania); Corneci, I.; Fadei, L. *J Cancer Res Clin Oncol* 94(2): 115-119; 1979.

The effect of 20-methylcholanthrene (20-MC: 10 mg, sc or im, followed in most cases by a second injection 74 days later) on the development of sarcomas in Jensen sarcoma-sensitive (S) and -resistant (R) Wistar and Long-Evans rats was studied. Tumors developed in 1/2 R and 1/2 S rats after 10 mg 20-MC and in 14/22 R rats and 7/19 S rats after 20 mg 20-MC. Tumors occurred 105-206 days postinjection at the site of the injection, and they evolved within 21-63 days. Histologically, fibroblastic sarcomas predominated. One of the 20-MC-induced sarcomas was transplanted from an R to an R rat and then to an S rat. It strongly immunized receptive rats against this tumor and also against the Jensen sarcoma. Antigenicity was maintained up to the 10th passage. (12 refs)

- 79-5640 Increased Integration of Viral Genome Following Chemical and Viral Treatment of Hamster Embryo Cells. (Eng) Casto, B. C. (Biotech, Inc., 2910 MacArthur Blvd., Northbrook, IL 60062); Miyagi, M.; Meyers, J.; DiPaolo, J. A. *Chem Biol Interact* 25(2/3): 255-269; 1979.

Treatment of hamster embryo cells with diverse classes of chemical carcinogens enhanced transformation by a carcinogenic simian adenovirus, SA7. Virus-transformed foci selected from plates pretreated with 3-methylcholanthrene (MCA), methyl methanesulfonate (MMS) or 7,12-dimethylbenz(a)anthracene (DMBA) and established as cell lines in culture contained equivalent amounts of SA7-viral genome. However, hamster embryo cultures treated with MMS or nickel sulfate had increased amounts of SA7 DNA integrated into cellular DNA when examined 2-9 days after chemical treatment and viral inoculation. An increased uptake of SA7 DNA was demonstrated in hamster cells treated with MMS during DNA repair synthesis in cells restricted in scheduled DNA synthesis by amino acid deprivation; addition of virus after the repair period did not result in an increased integration of viral DNA. These data suggest that the enhancement of viral oncogenesis by chemical carcinogens or mutagens may be

related to the formation of additional attachment sites in cellular DNA for insertion of viral DNA, thereby increasing the probability of viral transformation. (29 refs)

- 79-5641 Ascites Tumors in CBA Mice. Characterization of Two New Tumors, a Carcinoma and a Sarcoma in Solid and Ascites Form, with Regard to Cell Surface Properties and Transplantability. (Eng) Ryd, W. (Inst. Pathology, I, Univ. Goteborg, Goteborg, Sweden); Hagmar, B. *J Cancer Res Clin Oncol* 94(2): 185-199; 1979.

Two ascites tumors in syngeneic CBA mice (MCB 21-AA and MCB 31-AA) were studied, as were their solid progenitors, a sarcoma (MCB 21-SS) and a squamous cell carcinoma (MCB 31-SC) induced by gastric feeding of 20-methylcholanthrene. The ascites tumors showed differences in cell size, aggregatability, and growth rate. A certain number of tumors of each type demonstrated a PAS-positive "corona" at the periphery. MCA 21-SS and -AS (solid ascites tumor) were only weakly affected by concanavalin A (Con A), but they were heavily agglutinated by wheat germ agglutinin (WGA). MCB 21-AA was somewhat agglutinated by WGA but it was insensitive to Con A. MCB 31 showed the same pattern, but 31-SC was less agglutinable by WGA than 31-AS. Both ascites tumors showed higher electrophoretic mobilities than AS and SS/SC cells, the difference being greatest for 31-AA. MCB 21-AS and -SS and 31-AS had low thromboplastic activities, whereas MCB 31-SC had a high activity. MCB 21-SS, -AA, and 31-AA were hypotetraploid, and 31-SC was hypertetraploid. However, all lines showed considerable variation in chromosome number and chromosome markers. Suspensions of tumor cells were injected sc, ip, or iv into syngeneic and allogeneic mice. Relatively high cell doses were required for transplantation, even in syngeneic mice. Whole body x-radiation (300 rads) decreased the number of cells needed for transplantation ip and iv, except in the case of MCB 31-SC. Pulmonary metastases were common in animals dying following iv tumor injection; extrapulmonary metastases were rare. (30 refs)

- 79-5642 Lung Tumors in Mice Suckled by 3-Methylcholanthrene-treated Mothers. (Eng) Kinoshita, K. (Dept. Pathology, Chest Disease Res. Inst., Kyoto Univ, Kyoto 606, Japan); Takahashi, G.; Yasuhira, K. *Bull Chest Dis Res Inst Kyoto Univ* 12(1/2): 10-16; 1979.

Lung tumor incidence was studied in ICR mice suckled by mothers receiving the potent carcinogen 3-methylcholanthrene (3-MC: 5 mg in 0.5 ml sesame oil) by stomach tube on days 2 and 4 after delivery. Lung tumors were found in 28/46 male progeny and in 10/36 female progeny. Histologically, the tumors were adenomas and adenocarcinomas. No tumors developed in mice suckled by untreated mothers. 3-MC in milk and lung tissue was measured radiometrically to confirm its transfer via milk to the suckling mice. The amount of carcinogen in the lungs of the sucklings was <13.5 nanograms/mg of wet tissue, which agreed with the value obtained previously in fetal lungs when pregnant mice near term were treated po with 5 mg 3-MC. When analyzed by gas chromatography-mass spectrometry, ethanol-soluble fractions of milk from the stomachs of suckling mice contained the parent carcinogen and its 2-hydroxy, dehydro, and 1,2-dihydroxy derivatives. These metabolites are all carcinogenic in mice. (24 refs)

- 79-5643 Effect of Delay in Administration of 13-cis-Retinoic Acid on the Inhibition of Urinary Bladder Car-

cinogenesis in the Rat. (Eng) Becci, P. J. (Life Sciences Div., IIT Res. Inst., Chicago, IL 60616); Thompson, H. J.; Grubbs, C. J.; Brown, C. C.; Moon, R. C. *Cancer Res* 39(8): 3141-3144; 1979.

The effect of a delay of 13-cis-retinoic acid (RA) treatment on the inhibition of N-butyl-N-(4-hydroxybutyl) nitrosamine (OH-BBN)-induced urinary bladder carcinogenesis was studied in male Fischer 344 rats. Animals received a total of 1,200, 1,800, or 2,400 mg OH-BBN by gastric intubation over a period of 6 wk (100, 150, or 200 mg 2x/wk). At 1, 5, and 9 wk after the last OH-BBN dose, animals were started on a diet supplemented with RA (240 mg/kg of laboratory chow) or continued on laboratory chow. Animals were killed at 1 yr after the first carcinogen intubation for histological evaluation of the bladder. Feeding of RA reduced the incidence, av number, and severity of transitional cell carcinomas and of hyperplasia and cellular atypia. Furthermore, even a 9-wk delay in starting the RA feeding did not diminish its ability to inhibit bladder carcinogenesis. (10 refs)

79-5644 Interaction of Retinoic Acid and 3-Methylcholanthrene on the Fine Structure of Mouse Prostate Epithelium In Vitro. (Eng) Muller-Salamin, L. (Strangeways Res. Lab., Wort's Causeway, Cambridge CB1 4RN, England); Matter, A.; Lasnitzki, I. *J Natl Cancer Inst* 63(2): 485-495; 1979.

The effects of 3-methylcholanthrene (3-MC) and retinoic acid (RA) on the ultrastructure of AKR mouse prostate epithelium in organ culture were correlated with changes in cell proliferation. In intact glands before explantation, the epithelial cytoplasm showed concentric flat or globular cisternae of endoplasmic reticulum (ER) in both supranuclear and basal areas, a well-developed Golgi complex, secretory vesicles, and numerous microvilli at the luminal surface. After explantation, the cytoplasmic organelles, particularly the ER, regressed and tonofilaments appeared. The regression was largely prevented by RA. 3-MC induced considerable epithelial hyperplasia and squamous metaplasia. The ultrastructure of the newly formed cells revealed a complete loss of ER, Golgi apparatus, secretory vesicles, and microvilli, with the appearance of bundles of tonofilaments and a striking increase in the number of desmosomes. Administration of RA to explants pretreated with the carcinogen partially reversed the hyperplasia and squamous metaplasia. The tonofilaments disappeared and the number of desmosomes greatly decreased, whereas the ER, Golgi complex, secretory vesicles, and microvilli were largely reestablished. Planimetric measurements of the alveolar epithelium showed that the squamous transformation and its partial reversal by RA coincided with the rise and decline of epithelial hyperplasia. The data suggest that the restoration of secretory differentiation by RA was responsible for the initial breakdown of the hyperplastic epithelium, whereas the lowering of DNA synthesis by RA prevented further hyperplasia and kept all replication within normal limits. (27 refs)

79-5645 Chromosome Abnormalities Produced in Human Lymphocytes by Organic Extracts from River Water. (Eng) Doloy, M. T. (Departement de Protection, Section de Radiopathologie, Centre d'Etudes Nucleaires, B.P. No. 6, 92260 Fontenay-aux-Roses, France); Le Go, R.; Hardy, M.; Reillaudou, M. In: *Mutagen-induced Chromosome Damage in Man. Proceedings of a Symposium held in Edinburgh, Scotland, July 7-8, 1977*. Medical Research Council (Edinburgh, Scotland): 355 pp.; 311-315; 1978.

Chromosome abnormalities caused by organic extracts in river water were investigated in human lymphocytes in order to determine optimal experimental conditions for increasing the effect observed while maintaining mitotic activity. Particular emphasis was placed on the influence of the pollutant concentration in the culture and the pollutant-lymphocyte contact time. Chloroform extracts of organic substances from river water were used in a concentration of 200 µg/ml nutritive medium after complete evaporation. As a reference pollutant, 3,4-benzopyrene (BP) in dimethyl sulfoxide was introduced into the cultures at concentrations of 1 or 10 µg/ml. The standard technique involved culturing the lymphocytes for 2-3 days, with the micropollutant added at the beginning of culture time; or 4-5 day lymphocytes received the micropollutant after 24 hr of incubation. The long-lasting culture technique involved isolation of the lymphocytes, and incubation for 4 or 7 days at 37 C. The cells had a very low mitotic index because a low concentration of phytohemagglutinin was used in the medium. Three days after mitotic stimulation, the cells were treated according to standard methods for chromosomal observations. The cultures inoculated with pollutants were compared with control cultures. In control cultures, the frequency of chromosomal abnormalities was similar for all culture methods. More abnormalities were observed in the BP-treated cultures with a 4-day latent period than in the 2 or 3-day classical cultures. More abnormalities were observed in 3-day cultures than in 2-day cultures in which the same pollutant had been introduced. Similarly, more abnormalities were observed in the long-lasting cultures than in the 3-day classical cultures. In the 3-day cultures, a greater percentage of pollutants showed a significant effect, and this effect was more evident in the long-lasting cultures. Thus, the long-lasting culture technique is recommended for studies on the cytogenetic effects of pollutants. (no refs)

79-5646 Ellipticines as Potent Inhibitors of Microsomes-dependent Chemical Mutagenesis. (Eng) Lesca, P. (Laboratoire de Pharmacologie et de Toxicologie Fondamentales, 205 route de Narbonne, 31078 Toulouse Cedex, France); Lecoite, P.; Paoletti, C.; Mansuy, D. *Chem Biol Interact* 25(2/3): 279-287; 1979.

The inhibitory effects of ellipticine (E), 9-hydroxyellipticine (9-OHE), 9-fluoroellipticine (9-FE), and 7,8-benzoflavone (7,8-BF) on the mutagenicity of a large number of compounds were investigated. Aromatic amines, polycyclic hydrocarbons, fungal toxins, and azo compounds were used as mutagens in Ames bacterial assays with and without rat microsomal cytochrome P-450 monooxygenases (S9 mix). Most of the chemicals tested were mutagenic only in the presence of the S9 mix. E and 9-OHE exhibited weak mutagenicity in the presence of the S9 mix; 9-FE and 7,8-BF were not mutagenic with or without the mix. The presence of an OH or F group at position 9 decreased or suppressed the mutagenicity. 9-OHE greatly inhibited the mutagenicity of the activatable compounds tested, sometimes resulting in complete suppression of mutagenicity. In all cases except that of aflatoxin B₁, the amount of 9-OHE that decreased mutagenicity by 50% was lower than the amount of mutagen used in the test. With respect to benzo(a)pyrene-induced mutagenesis, 9-OHE and 9-FE were more potent inhibitors than E. 9-OHE was 10 times more potent in inhibiting the mutagenicities of benzo(a)pyrene, aflatoxin B₁, 3-methylcholanthrene, and ethidium bromide than 7,8-BF. It appears possible to design derivatives of E that lack mutagenicity in themselves but may be useful in vivo as potent inhibitors of chemically induced mutagenesis. (21 refs)

79-5647 The Role of Cytochrome P-450 Forms in 2-Aminoanthracene and Benz(a)pyrene Mutagenesis.

(Eng) Norman, R. L. (Dept. Biochemistry, Scripps Clinic and Res. Foundation, La Jolla, CA 92037); Muller-Eberhard, U.; Johnson, E. F. *Biochem Biophys Res Commun* 89(1): 195-201; 1979.

The role of four forms (2,3,4, and 6) of cytochrome P-450 from rabbit liver in the metabolic activation of two suspected carcinogens, 2-aminoanthracene (AA) and benzo(a)pyrene (BP), was studied using *Salmonella typhimurium* strain TA98. The number of bacterial revertants increased in a linear fashion for both AA and BP mutagenesis with increasing incubation time at 37 C. Metabolic activation of both compounds to mutagens increased as a linear function of the concentrations of form 4 to 6 up to 100 picomoles of cytochrome P-450 per incubation. Thus, the amount of cytochrome P-450 was rate-limiting. Form 4 produced 10-30 times more revertants with AA than a control incubation in which cytochrome P-450 was omitted. BP mutagenesis appeared to be catalyzed almost exclusively by form 6, which produced 6-15 times the number of revertants observed in control incubations. In both cases, the other forms of cytochrome P-450 produced at most three times more revertants than control incubations. The results indicate that specific cytochrome P-450 forms preferentially activate particular mutagens. (30 refs)

79-5648 Insectan Aryl Hydrocarbon Hydroxylase Generates Benzo(a)Pyrene Metabolites That Bind to Protein and DNA. (Eng) Anderson, R. S. (Donald S. Walker Lab., Sloan-Kettering Inst. Cancer Res., 145 Boston Post Rd., Rye, NY 10580). *Comp Biochem Physiol [C]* 63(1): 17-20; 1979.

A study suggesting that insectan microsomal oxidases can metabolically activate carcinogenic polycyclic hydrocarbon is reported. Oxidation of benzo(a)pyrene by *Spodoptera eridania* microsomal enzymes generated metabolites that bound to biological macromolecules. Aryl hydrocarbon hydroxylase induction by the topical application of polychlorinated biphenyls in larvae stimulated benzo(a)pyrene metabolite binding. Inhibition of aryl hydrocarbon hydroxylase activity decreased metabolite binding. (31 refs)

79-5649 Mutagenesis of Certain Benzo(a)pyrene Phenols In Vitro Following Further Metabolism by Mouse Liver. (Eng) Owens, I. S. (Developmental Pharmacology Branch, Natl. Inst. Child Health and Development, NIH, Bethesda, MD 20014); Koteen, G. M.; Legraverend, C. *Biochem Pharmacol* 28(10): 1615-1622; 1979.

The consequences of the metabolic activation of certain phenols of benzo(a)pyrene (BP) were examined, along with how conjugation reactions may alter these effects. Phenols produced enzymatically were of particular interest, especially 3-hydroxybenzo(a)pyrene (3-OH-BP). Low concentrations of 1-OH- and 3-OH-BP in the presence of NADPH and the liver S-9 fraction from 3-methylcholanthrene (3-MC)-treated C57BL/6N mice were up to three times more mutagenic than BP in the *Salmonella typhimurium* LT₂ tester strain TA98. The level of mutagenicity rose with increasing phenol or S-9 protein concentration. In this system, 9-OH-BP was slightly mutagenic, but 2-OH-, 7-OH-, and 12-OH-BP were not mutagenic at low concentrations. The S-9 fraction from 3-MC-treated DBA/2N mice or phenobarbital-treated C57BL/6N mice did not support significant levels of mutagenesis. The high level of mutagenicity by 1-OH- or 3-OH-BP was inhibited by α -naphthoflavone but not by metyrapone, 1,2-epoxy-3,3,3-trichloropropane, or glutathione. The substrate for

uridine diphosphate (UDP)-glucuronosyltransferase, UDP-glucuronic acid, prevented more than half of the mutagenicity caused by the further metabolism of 1-OH- and 3-OH-BP. The combination of UDP-glucuronic acid and UDP-N-acetylglucosamine provided an even higher level of protection. The addition of the substrate for sulfotransferase(s), 3'-phosphoadenosine 5'-phosphate sulfate, also prevented about half of the mutagenesis caused by 1-OH- or 3-OH-BP. (40 refs)

79-5650 Mutation of Human Cells by Kerosene Soot. (Eng) Skopek, T. R. (Dept. Nutrition and Food Science, Massachusetts Inst. Technology, Cambridge, MA 02139); Liber, H. L.; Kaden, D. A.; Hites, R. A.; Thilly, W. G. *J Natl Cancer Inst* 63(2): 309-312; 1979.

A human lymphocyte mutation assay was used to determine the mutagenicity of a methylene chloride extract of kerosene soot and two components of the extract, benzo(a)pyrene (BP) and cyclopenta(cd)pyrene (CP). The polycyclic aromatic hydrocarbon fraction of kerosene soot induced forward mutations in human diploid lymphoblasts when coincubated with a Sprague-Dawley rat liver postmitochondrial supernatant. BP was not mutagenic at the concentration found in the soot extract (0.52 μ g/ml), although it was active at higher concentrations. The amount of CP present could account for approx 8% of the total mutations observed with the soot. The results were compared with data obtained previously in a similar mutation assay in *Salmonella typhimurium*. The protocol described permits the facile assay of mutation at the *hprt* locus in human lymphoblasts; this mutation is induced by compounds or complex mixtures requiring mixed-function oxygenase activity for metabolism to genetically active derivatives. 79-5651 Metabolism of Benzo(a)pyrene in Hamster Embryo Cells. Effect of the Concentration of Benzo(a)pyrene on Its Metabolism. (Eng) Nemoto, N. (Dept. Experimental Pathology, Cancer Inst., 1-37-1, Kami-Ikebukuro, Toshima-ku, Tokyo 170, Japan); Hirakawa, T.; Takayama, S. *Chem Biol Interact* 25(2/3): 177-188; 1979.

The metabolism of benzo(a)pyrene (BP) by hamster embryo cells was studied. The production of water-soluble metabolites, shown to be conjugates with glucuronic acid, depended on BP concentration. With increased BP concentration the amount of glucuronic acid conjugates increased, but the proportion of conjugates in BP or its metabolites present in the medium decreased. The metabolites extracted with ethylacetate were *trans*-7,8-dihydrodiol-BP (7,8-dihydrodiol) and *trans*-9,10-dihydrodiol-BP (9,10-dihydrodiol), but large peaks of phenolic metabolites were found by high pressure liquid chromatography (HPLC) after digestion of the medium with β -glucuronidase. Therefore, BP was metabolized to oxygenated forms, and of these, most of the phenolic metabolites and parts of the dihydrodiols were conjugated with glucuronic acid. The proportions of dihydrodiols to phenols, estimated by HPLC after β -glucuronidase digestion, decreased when the BP concentration was decreased. The results suggest that dihydrodiols are less readily glucuronidated than phenols and so may be metabolized further to metabolites other than glucuronic acid conjugates. (24 refs)

79-5652 Metabolism and Toxicity of Benzo(a)pyrene-4,5-oxide in the Isolated Perfused Rat Liver. (Eng) Smith, B. R.

(Lab. Pharmacology, Natl. Inst. Environmental Health Sciences, Research Triangle Park, NC 27709); Bend, J. R. *Toxicol Appl Pharmacol* 49(2): 313-321; 1979.

[G-³H]benzo(a)pyrene-4,5-oxide ([G-³H]BP-4,5-oxide) in isolated perfused rat livers was metabolized predominantly to conjugates (mainly thioether derivatives) and to a lesser extent to the dihydrodiol. The metabolites were released from the livers into the vascular circulation, but biliary excretion was the major route of removal of the metabolic products. BP-4,5-oxide caused periportal damage and was covalently bound to tissue DNA, RNA, and protein. BP-4,5-oxide metabolism in the isolated liver and in intact rats was qualitatively and quantitatively similar. (40 refs)

79-5653 Deoxyribonucleic Acid Binding of 3-Hydroxy- and 9-Hydroxybenzo(a)pyrene Following Further Metabolism by Mouse Liver Microsomal Cytochrome P₁-450. (Eng) Owens, I. S. (Developmental Pharmacology Branch, Natl. Inst. Child Health and Human Development, NIH, Bethesda, MD 20014); Legraverend, C.; Pelkonen, O. *Biochem Pharmacol* 28(10): 1623-1629; 1979.

Since 3-hydroxy- and 9-hydroxybenzo(a)pyrene (3-OH- and 9-OH-BP) are the major primary metabolites of benzo(a)pyrene (BP) and since certain phenols are strong mutagens, the DNA-binding activity of these compounds was investigated, along with the effects of various modifiers on binding. In the presence of NADPH and microsomes from 3-methylcholanthrene (3-MC)-treated C57BL/6N mice, [³H]3-OH-BP was metabolized to reactive intermediates that covalently bound to deproteinized salmon sperm DNA in vitro. Enzymatically digested DNA, containing bound [³H]3-OH-BP derivatives, generated an elution profile upon Sephadex LH20 chromatography that resembled similar chromatograms with [³H]BP. All peaks resulting from [³H]BP activation appeared to be represented in [³H]3-OH-BP activation, except that several peaks that emerged near the end of the eluting gradient of methanol and water were much reduced. Notably, a peak designated E that is attributed to BP-7,8-diol-9,10-oxide binding in [³H]BP incubations, was also prominently represented in incubations with [³H]3-OH-BP. Radioactivity in all of these peaks was inhibited if one-seventh the concentration of 1-OH-BP was included in the incubation with [³H]3-OH-BP. Microsomes from 3-MC-treated DBA/2N mice caused insignificant binding. Uridine diphosphate (UDP)-glucuronic acid markedly reduced all peaks except E, and 1,2-epoxy-3,3,3-trichloropropane reduced all peaks except C and E. 9-OH-BP was further metabolized to DNA binding species by microsomes from either 3-MC-treated DBA/2N or C57BL/6N mice. UDP-glucuronic acid prevented about 50% of the binding with microsomes from DBA/2N mice but not with microsomes from C57BL/6N mice. UDP-glucuronic acid did prevent binding in some of these same peaks when [³H]-BP was the starting substrate with microsomes from C57BL/6N mice. UDP-glucuronic acid did not prevent binding in peak E in incubations with [³H]BP or [³H]3-OH-BP. (26 refs)

79-5654 Interaction of Benzo(a)pyrene and a Hyperplastic Agent in Epidermal Nuclear Enlargement in the Mouse. A Dose-Response Study. (Eng) Ingram, A. J. (British Industrial Biological Res. Assoc., Woodmansterne Road, Carshalton, Surrey, England). *Chem Biol Interact* 26(1): 103-113; 1979.

The effects of various dose levels of benzo(a)pyrene (BP: 0.4-2,500

µg/ml on nuclear size in To strain mouse interfollicular epidermis were determined over a 3-day period. Topical application of BP was made with or without croton oil (CO: 0.1% or 0.5%) in acetone, toluene, or methyl ethyl ketone (MEK). Nuclear size was measured in histological sections either manually or by the Quantimet Image Analyser. Vehicle controls treated with 0.1% or 0.5% CO in acetone or MEK gave rise to epidermal hyperplasia with some nuclear enlargement; toluene without CO produced a similar response. When BP was applied in a vehicle capable of inducing hyperplasia, the nuclear enlargement produced was greater than that produced by either the vehicle control or BP in a nonirritant vehicle. The enhancement of the response to BP when BP was tested in the presence of a hyperplastic agent resulted in lower concentrations of BP being detectable. As the levels of BP detectable by nuclear enlargement under these conditions compared reasonably well with those detectable in long-term tests, this system might be useful as a short-term test for carcinogens. (19 refs)

79-5655 The Effects of Harman and Norharman on the Metabolism of Benzo(a)pyrene in Isolated Perfused Rat Lung and in Rat Lung Microsomes. (Eng) Vahakangas, K. (Dept. Pharmacology, Univ. Oulu, SF-90 220 Oulu 22, Finland); Pelkonen, O. *Biochem Pharmacol* 28(10): 1591-1596; 1979.

A comparative study was made of the effects of harman (HM) and norharman (NHM), nitrogen-containing pyrolysis products of amino acids present in cigarette smoke, on the metabolism of benzo(a)pyrene (BP) in Sprague-Dawley rat lung microsomes in vitro and in isolated perfused rat lung. In the microsomes, HM and NHM inhibited the metabolism of BP to dihydrodiols, phenols, and quinones at concentrations >0.05 mM. The formation of BP-7,8-dihydrodiol and BP-9,10-dihydrodiol was inhibited more than that of BP-4,5-dihydrodiol. No appreciable differences in inhibition were seen between microsomes from control or 3-methylcholanthrene-pretreated rats. In isolated perfused rat lung, 1 mM HM in the perfusion fluid inhibited the formation of all ethyl acetate-soluble metabolites of BP except for BP-9,10-dihydrodiol, and it inhibited the total covalent binding of BP metabolites to lung tissue macromolecules. At 0.03 mM, HM seemed to increase the formation of metabolites other than BP-7,8-dihydrodiol without changing the total covalent binding. These results suggest that at most concentrations, HM and NHM inhibit BP metabolism and covalent binding both in lung microsomes in vitro and in isolated perfused rat lung. (44 refs)

79-5656 Toxicity of Metabolic Benzo(a)pyrenediones to Cultured Cells and the Dependence upon Molecular Oxygen. (Eng) Lorentzen, R. J. (Div. Biophysics, Sch. Hygiene and Public Health, Johns Hopkins Univ., Baltimore, MD 21205); Lesko, S. A.; McDonald, K.; Ts'o, P. O. *Cancer Res* 39(8): 3194-3198; 1979.

The toxicity of the three quinone metabolites of benzo(a)pyrene (BP), the 6,12-, 1,6-, and 3,6-dione, to cultures of Syrian hamster embryo cells was studied. At low concentrations (0.67 and 2.70 µg/ml), all three diones were toxic to the cells. The effect was dose-dependent, and it was greater at 48 hr than at 24 hr after treatment. BP 6,12-dione was slightly less effective than the other two diones. The reduction in cell number observed after treatment with these metabolites was the result of direct cell killing and inhibition of growth, since DNA synthesis was inhibited very early after treatment with BP 1,6-dione, when little cell death had occurred.

The rate of RNA synthesis was also inhibited by treatment of cells with BP 3,6-dione. These actions of the diones toward hamster cells could be eliminated or substantially reduced by the removal of oxygen from the growth medium and atmosphere in which the cells were incubated. In contrast, anaerobic conditions did not reduce the cytotoxicity observed with the alkylating agent ethyl methanesulfonate. These results support the hypothesis that BP diones, and other biologically active quinones, owe their activity to oxidation-reduction cycles involving quinone, hydroquinone, and molecular oxygen. The reactive reduced oxygen radicals and semi-quinone radicals formed during these cycles may be responsible for the observed cellular injury and inhibition of cellular processes. (30 refs)

- 79-5657 The Metabolism of Benzo(a)pyrene by Cytochrome P-450 in Transformable and Nontransformable C3H Mouse Fibroblasts. (Eng) Gehly, E. B. (Los Angeles County-Univ. Southern California Comprehensive Cancer Center, Los Angeles, CA 90033); Fahl, W. E.; Jefcoate, C. R.; Heidelberger, C. *J Biol Chem* 254(12): 5041-5048; 1979.

The microsomal metabolism of benzo(a)pyrene (BP) and its enhancement by inducers of aryl hydrocarbon hydroxylase (AHH) were studied in three C3H mouse fibroblast cell lines and in C3H mouse liver and lung. The cell lines examined included C3H/10T1/2CL8, a line that can be transformed by BP; CVP3SC6, a line that cannot be transformed by BP; and C3H/10T1/2CL16, a transformed cell line derived from 3-methylcholanthrene-treated C3H/10T1/2CL8 cells. Of four polycyclic hydrocarbons examined, benz(a)anthracene (BA) was found to be the most effective inducer of AHH activity, followed by BP and 7,12-dimethylbenz(a)anthracene; there was a complete absence of induction by 3-methylcholanthrene. The extent of induction in all three cell lines was dependent on the time after seeding that the inducer was added. The high-pressure liquid chromatographic profile of the BP metabolites was qualitatively identical for microsomes from all three cell lines, and it differed from the metabolism by liver and lung microsomes in that the cells did not produce detectable levels of BP-4,5-hydrodiol. The reduced CO cytochrome P-450 difference spectra of control and induced microsomes from all three cell lines showed a characteristic shift to shorter wavelengths after induction with BA. The specific activity of cytochrome P-450 in the cell microsomes closely paralleled the BP metabolizing activity, as measured in the AHH and high-pressure liquid chromatography assays. (34 refs)

- 79-5658 Differences in Benzo(a)pyrene Metabolic Profile in Rat and Mouse Ovary. (Eng) Mattison, D. R. (Pregnancy Res. Branch, Natl. Inst. Child Health and Human Development, NCI, NIH, Bethesda, MD 20205); West, D. M.; Menard, R. H. *Biochem Pharmacol* 28(13): 2101-2104; 1979.

Differences in polycyclic aromatic hydrocarbon (PAH) ovotoxicity and ovarian carcinogenicity between rats and mice suggest differences in toxic and nontoxic pathways of PAH metabolism in the rat and mouse ovary. Ovarian aryl hydrocarbon hydroxylase (AHH) activity was approx two times greater in B6 mice than in Sprague-Dawley rats, in both control and 3-methylcholanthrene (3-MC)-treated animals. No oocytes were destroyed in 3-MC-treated rats, but 87% were destroyed in treated mice. The gonads of the two species differed in their benzo(a)pyrene metabolic pathways. The lower production of the 7,8-diol by rat ovarian

monooxygenase is consistent with the greater resistance of the rat ovary to PAH ovotoxicity and ovarian carcinogenicity. (12 refs)

- 79-5659 Fluorescence Properties of a Benzo(a)pyrene 7,8-Dihydrodiol 9,10-Oxide-DNA Adduct. Conformation and Effects of Intermolecular DNA Interactions. (Eng) Prusik, T. (Squibb Inst. Medical Res., New Brunswick, NJ 08903); Geacintov, N. E. *Biochem Biophys Res Commun* 88(3): 782-790; 1979.

The pyrenelike fluorescence of the covalent benzo(a)pyrene (BP) diol-epoxide-DNA complex prepared by reacting the 7,8-dihydrodiol-9,10-oxide of BP (BPDE) with DNA in aqueous soln in vitro was investigated. This fluorescence was sensitive to molecular oxygen, to the concentration of native DNA, and to the ionic strength (KCl concentration) of the soln, but it was insensitive to the concentration of denatured DNA. These effects are related to the conformation of the pyrenelike chromophore of BPDE. Most of the fluorescence of a dilute soln of the DNA-bound BP derivative originated from binding sites in which the pyrene moiety was not intercalated between the DNA base pairs, but was located on the outside of the DNA double helix. (18 refs)

- 79-5660 Comparison of Benzo(a)pyrene and (-)-trans-7,8-Dihydroxy-7,8-dihydrobenzo(a)pyrene Metabolism in Human Blood Monocytes and Lymphocytes. (Eng) Okano, P. (Chemical and Physical Carcinogenesis Branch, NCI, NIH, Bethesda, MD 20205); Miller, H. N.; Robinson, R. C.; Gelboin, H. V. *Cancer Res* 39(8): 3184-3193; 1979.

Benzo(a)pyrene (BP) and (-)-trans-7,8-dihydroxy-7,8-dihydrobenzo(a)pyrene [(-)-trans-7,8-diol] metabolism in human blood monocytes (MC's) and lymphocytes (LC's) was analyzed by high-pressure liquid chromatography, a procedure that required relatively low numbers of cells. The BP metabolite pattern included large amounts of the 7,8-diol, low or moderate levels of the 4,5-diol, and barely detectable levels of the 9,10-diol; at least three phenols, 3-, 7-, and 9-hydroxy-BP; and two major separable quinones, the BP-1,6- and 3,6-diones. BP metabolite patterns formed by benz(a)anthracene (BA)-induced MC's and LC's from the same individual showed that each cell type has characteristic differences in the relative ratios of BP metabolites formed. Relatively greater proportions of the 7,8-diol and 9-hydroxy-BP were synthesized by MC's, but LC's formed relatively higher levels of 3-hydroxy-BP and the BP quinones. Thus, it appears that MC's and LC's contain different patterns of cytochrome P-450 (CC P-450) mixed-function oxidases or metabolically related enzymes that are active in BP metabolism. The ratio of BP metabolites formed by BA-induced to that of control MC's and LC's was greater for the 7- and 9-hydroxy-BP's and smaller for 3-hydroxy-BP and the 7,8-diol in most samples examined. The total amounts of BP metabolites formed were quantitatively higher in BA-induced cells. These data suggest that BA induction was selective and favored the formation of certain forms of CC P-450 that change the metabolite patterns in induced cells. Both noninduced and BA-induced MC's and LC's metabolized the (-)-trans-7,8-diol further to highly mutagenic 7,8-diol-9,10-epoxides. Analysis of the ethyl acetate-extractable tetrols and triols demonstrated that the major diol-epoxide formed was *r*,7-*t*-8-dihydroxy-*t*-9,10-oxy-7,8,9,10-tetrahydro-BP. The results indicate that MC's and LC's exhibit different metabolite profiles, as do BA-induced and control cells. BA induction appears to favor BP over 7,8-diol metabolism, suggesting that the induction may lead to a greater ratio of detoxified to activated products relative to the ratio form-

ed in control cells. The results also show that the amount of 7,8-diol metabolism in BA-treated cells is either similar to or only slightly greater than that in control cells. This is in contrast to BP metabolism, which is stimulated 2- to 4-fold by BA. Thus, the form of CC P-450 metabolizing the 7,8-diol to diol-epoxides is relatively uninducible compared to those CC P-450 forms metabolizing BP. (46 refs)

- 79-5661 Effects of Smoking on Benzo(a)pyrene Metabolism by Human Placental Microsomes. (Eng) Vaught, J. B. (Dept. Experimental Therapeutics, Roswell Park Memorial Inst., Buffalo, NY 14263); Gurtoo, H. L.; Parker, N. B.; LeBoeuf, R.; Doctor, G. *Cancer Res* 39(8): 3177-3183; 1979.

Data demonstrating that the human placenta is capable of metabolizing benzo(a)pyrene (BP) to potentially carcinogenic metabolites are presented. Placentas were collected at term from a series of 21 women, 13 smokers and 8 nonsmokers. Microsomes were prepared and used in the following studies of BP metabolism: measurements of aryl hydrocarbon hydroxylase (AHH) and epoxide hydase levels, high-pressure liquid chromatographic (HPLC) analysis of BP metabolites, and assay of DNA-binding activation. DNA-binding adducts were further characterized by Sephadex LH-20 chromatography. AHH activity was much higher in smokers than in nonsmokers. Epoxide hydase activity with styrene oxide as the substrate was similar in the two groups. HPLC analysis showed much greater formation of dihydrodiols, quinones, and phenols by microsomes from smokers. The amount of benzo(a)pyrene-7,8-dihydrodiol was almost equal to the amount of phenols produced by the microsomes of the smokers. Sephadex LH-20 analysis of DNA binding resulted in only one major BP-DNA adduct when microsomes from smokers were used; this peak corresponded to benzo(a)pyrene 7,8-diol-9,10-oxide bound to DNA nucleoside(s). (54 refs)

- 79-5662 Dexamethasone-inhibited Aldosteroma (Variant of Primary Aldosteronism). (Rus) Zefirova, G. S. (Dept. Endocrinology, Central Inst. Advanced Training Physicians, Moscow, USSR); Gerasimenko, P. P.; Mirzaiants, G. G.; Ametov, A. S. *Ter Arkh* 51(6): 96-99; 1979.

A 38-yr-old woman with a history of hypertension presented with constant headache, asthenia, and periodic palpitation. Arteriography showed a shadow in the region of the left adrenal. The plasma aldosterone level was 800 picograms (pg)/ml, compared with 89.6 pg/ml in healthy controls. A diagnosis of dexamethasone-inhibited aldosteroma of the left adrenal was made. Administration of dexamethasone (4 mg/day, po, for 6 days) resulted in normalization of the blood pressure and the blood aldosterone level to 84 pg/ml. (13 refs)

- 79-5663 Metabolism of Prolactin in Mice with a High Incidence of Mammary Tumours: Evidence for Greater Conversion into a Non-immunoassayable Form. (Eng) Sinha, Y. N. (Lutcher Brown Center Diabetes and Endocrinology, Scripps Clinic and Res. Foundation, La Jolla, CA 92037); Baxter, S. R. *J Endocrinol* 81(3): 299-314; 1979.

Experiments were conducted to determine whether prolactin (PL) is immunologically activated in the circulation of cancer-prone

mice. Monomeric mouse PL containing small amounts of 125 I-labeled PL was administered to adult female mice of a high (C3H/St) and low (C57BL/St) mammary tumor strain. Their endogenous PL had been suppressed with 2-bromo- α -ergocryptine. The chromatographic profile, on Sephadex G-100, of PL in the serum of mice injected with mouse PL was compared by direct measurement (radioactivity count) and by radioimmunoassay (RIA) at several intervals after injection. With both methods, the injected hormone was found in the serum in predominantly two molecular sizes, the so-called "big" and "little" forms. Although little PL in both strains constituted a constant 80% of the total PL level at most intervals by direct measurement, it comprised a comparatively smaller proportion by RIA. In addition, the RIA-determined little PL, after reaching max levels at 15 min, progressively decreased with time, the decrease being greater in the C3H/St than in the C57BL/St strain. Similar experiments with mouse growth hormone revealed no such discrepancies between the radioactivity counts and the RIA measurements. A fraction of big and little forms in the C3H/St strain failed to precipitate completely after the material had been incubated with an antiserum to mouse PL. These results demonstrate that the PL injected into mice is metabolized in serum into two nonimmunoreactive forms, one that elutes with the same elution volume on a Sephadex G-100 column as the monomer and the other that elutes as the big form. Furthermore, the loss of immunoreactivity of monomeric mouse PL is greater in the C3H/St strain than in the C57BL/St strain. Endogenous immunoreactive PL, on the other hand, was found mainly in the big form in the serum of C3H/St mice under basal conditions, whereas it was present only in the little form in C57BL/St mice, even though pituitary extracts of both strains contained mainly the little form. These results support the concept that monomeric PL in the systemic circulation of C3H/St mice is largely in a nonimmunoreactive form. (34 refs)

- 79-5664 Plasma Melatonin, Luteinizing Hormone, Follicle-stimulating Hormone, Prolactin, and Corticoids in Two Patients with Pinealoma. (Eng) Kennaway, D. J. (Dept. Obstetrics and Gynaecology, Queen Elizabeth Hosp., Adelaide, South Australia); McCulloch, G.; Matthews, C. D.; Seamark, R. F. *J Clin Endocrinol Metab* 49(1): 144-145; 1979.

Plasma melatonin was not detectable in two patients with pinealoma, but gonadotropin and cortisol levels were within the normal range. One patient, a 43-yr-old man, had low prolactin levels and the other patient, a prepubertal boy, had elevated levels. The clinical value of melatonin as a potential marker for pineal tumors is questionable. (5 refs)

- 79-5665 Mammary Tumour Incidence in Relation to the Pattern of Oestrous Cycles in Mice. (Eng) Nagasawa, H. (Pharmacology Div., Natl. Cancer Center Res. Inst., Tsukiji 5-1-1, Chuo-ku, Tokyo 104, Japan); Yanai, R.; Taniguchi, H.; Hayashi, S. *Horm Res* 10(2/3): 123-129; 1979.

The estrous cycles of SHN and SLN mice, two new strains that exhibit a high and a low mammary tumor incidence, respectively, were compared. These mice originated from the same stock of Swiss albino mice. At the age of 3-4 mo, SHN mice showed much longer cycles with continual diestrous periods than SLN mice. The av lengths of the cycles and diestrous periods were, respectively, 8.3 and 6.0 days in SHN mice and 4.6 and 2.5 days in SLN mice. Furthermore, a distinct alteration in cycle pattern from an SHN to an SLN type was associated with a complete reduction in mam-

mary tumor incidence in highly inbred C3H/He female mice maintained by brother x sister mating with no selection for mammary tumorigenesis. The relation between the pattern of estrous cycles and mammary tumorigenesis is considered from the viewpoint of the endogenous hormonal milieu and the responsiveness of target organs. (16 refs)

- 79-5666 Virilizing Syndrome Associated with an Adrenal Cortical Adenoma Secreting Predominantly Testosterone. (Eng) Schteingart, D. E. (Univ. Hosp., Room S3450, Ann Arbor, MI 48109); Woodbury, M. C.; Tsao, H. S.; McKenzie, A. K. *Am J Med* 67(1): 140-146; 1979.

A 22-yr-old woman with virilization and mild Cushing's syndrome associated with a testosterone (TS)-secreting left adrenal adenoma is described. The patient had a high serum TS level, a mildly elevated urinary 17-ketosteroid level, and a normal plasma cortisol level. The basal level of cortisol secretion was normal but with evidence of autonomy. The tumor was capable of secreting TS, cortisol, dehydroepiandrosterone (DHEA), and 17 β -estradiol (E2), but the capacity was greatest for TS, DHEA, and E2. (29 refs)

- 79-5667 Teratogenesis and Carcinogenesis in Rat Offspring After Transplacental and Transmammary Exposure to Diethylstilbestrol. (Eng) Vorherr, H. (Dept. Obstetrics-Gynecology, Univ. New Mexico, Sch. Medicine, Albuquerque, NM 87131); Messer, R. H.; Vorherr, U. F.; Jordan, S. W.; Kornfeld, M. *Biochem Pharmacol* 28(12): 1865-1877; 1979.

Female offspring of pregnant and/or lactating rats that received diethylstilbestrol (DES: ≥ 0.05 mg/kg/day, sc) had abnormal development of the urogenital sinus. Vaginal adenosis, endometrial squamous metaplasia, and genital malignancy were encountered in 20%-40% of these offspring. In exposed male offspring, hypospadias, phallic hypoplasia, inhibition of growth and descent of testes, and abnormalities of Wolffian derivatives were observed. (53 refs)

- 79-5668 Glandular Dysplasia in Diethylstilbestrol-associated Vaginal Adenosis. A Case Report and Review of the Literature. (Eng) Antonioli, D. A. (Dept. Pathology, Beth Israel Hosp., 330 Brookline Ave., Boston, MA 02215); Rosen, S.; Burke, L.; Donahue, V. *Am J Clin Pathol* 71(6): 715-721; 1979.

In a 21-yr-old nulliparous woman with diethylstilbestrol (DES)-associated vaginal adenosis, dysplastic glands were identified and examined by light and electron microscopy. Transitions between normal and dysplastic glands were documented in subserial sections. These alterations may characterize an intermediate phase in the development of clear-cell adenocarcinoma of the vagina. Documented glandular dysplasia in adenosis is rare: in an evaluation of 550 DES-exposed women, only two cases (including the present one) were found. (15 refs)

- 79-5669 Adenosis-like Lesions and Other Cervicovaginal Abnormalities in Mice Treated Perinatally with Estrogen. (Eng) Plapinger, L. (Population Council, Rockefeller Univ., 1230

York Ave., New York, NY 10021); Bern, H. A. *J Natl Cancer Inst* 63(2): 507-518; 1979.

The effects of perinatal estrogen treatment on cervicovaginal histogenesis were determined in female mice from three inbred strains (BALB/cCrgl, C3H/Crgl, and C57BL/Crgl) and one noninbred stock [RU:NCS (RU)]. The mice were treated with estradiol benzoate (EB), diethylstilbestrol (DES), or sesame oil and killed on postnatal days 30-36. A combined prenatal and neonatal regime of EB injections resulted in the abnormal presence of columnar epithelium in the vaginal fornices of some of the mice from each strain or stock. The same epithelial abnormalities were also present in the vaginal fornices of 30-day-old RU:NCS(RU) mice that had been treated only neonatally with EB or DES. The incidence of these lesions was 40%-67% in mice treated prenatally and neonatally with EB, 68% in the neonatal EB treatment group, and 100% in the neonatal DES treatment group. The columnar cells were arranged either as single layers in areas of the fornical lining epithelium or as glandlike or cystic structures in the subepithelial stroma. No cells of this type were detected in any of the samples from sesame oil-inoculated control mice. No comparable epithelial lesions were detected in the common cervical canal of the perinatally estrogen-treated animals, but this treatment consistently resulted in gross structural abnormalities at this site. (25 refs)

- 79-5670 Long-Term Effects of Neonatal Estrogen Treatment on Mitogen Responsiveness of Mouse Spleen Lymphocytes. (Eng) Kalland, T. (Inst. Anatomy, Arstadvei 19, 5000 Bergen, Norway); Strand, O.; Forsberg, J. G. *J Natl Cancer Inst* 63(2): 413-421; 1979.

The effect of neonatal estrogen treatment on the in vitro responsiveness of spleen lymphocytes from adult mice to T- and B-cell mitogens was studied. Neonatal female NMRI mice were given sc injections of olive oil (controls) or daily doses of corticosterone (10 μ g), 17 β -estradiol (10 μ g), or diethylstilbestrol (DES: 0.01, 0.1, 1, or 5 μ g) for the first 5 days after birth. The 5- μ g dose of DES resulted in a persistently reduced in vitro mitogen response of spleen lymphocytes from 6-, 10-, and 18-wk-old and 17-mo-old females to concanavalin A or bacterial lipopolysaccharide. DES injections from day 6 through day 10 did not influence the later mitogen response. Treatment of ovariectomized 10-wk-old females with 5 μ g DES for 5 days resulted in a statistically nonsignificant reduced mitogen response 24 hr after the last injection. Four weeks later, the mitogen response was the same in experimental and control females. Different possible mechanisms for the persistent effect on the mitogen response are discussed. Neonatal DES treatment not only resulted in persistent changes in the cervicovaginal epithelium and in the hypothalamic-pituitary gland control system, but also in the spleen lymphocyte mitogen response. The altered mitogen response should be a stimulus for a detailed analysis of the immune system in women exposed to DES during fetal life, some of whom develop clear cell adenocarcinoma of the uterine cervix and vagina later in life. - 79-5671 Association of Diethylstilbestrol Exposure In Utero with Cryptorchidism, Testicular Hypoplasia and Semen Abnormalities. (Eng) Gill, W. B. (Dept. Surgery (Urology), Univ. Chicago, Chicago, IL); Schumacher, G. F.; Bibbo, M.; Straus, F. H.; Schoenberg, H. W. *J Urol* 122(1): 36-39; 1979.

The occurrence of genital tract abnormalities among 308 men exposed to diethylstilbestrol and 307 men exposed to a placebo 25 yr

previously (in utero) was studied. The incidences of epididymal cysts and testicular hypoplasia were significantly greater among the DES-exposed men (20.8% and 8.4% for the two conditions, respectively) than among the placebo controls (4.9% and 1.9%, respectively). Cytological examination of the fluid aspirated from the epididymal masses of nine DES-exposed men showed only epithelial cells and amorphous precipitates without any material suggestive of malignancy. Similarly, the urine and prostatic fluid of DES-exposed and control men were negative for tumor cells. Of the 26 DES-exposed men with testicular hypoplasia, 65% had a history of cryptorchidism, compared with only 1/6 of the controls with testicular hypoplasia. The DES-exposed and control subjects did not differ significantly with respect to levels of circulating blood hormones. The av sperm density was somewhat decreased in the DES-exposed men compared with controls, and the av Eliasson score (sperm count, sperm motility, motility grade, and sperm morphology) was significantly higher in the DES-exposed group (4.9) than in the controls (2.5). 79-5672 Effects of Oral Contraceptives and Pregnancy on Melanomas (Letter to Editor). (Eng) Lerner, A. B. (Yale Univ. Sch. Medicine, New Haven, CT 06510); Nordlund, J. J.; Kirkwood, J. M. *N Engl J Med* 301(1): 47; 1979.

Three cases are reported of female patients in whom the development or metastasis of a melanoma was associated with estrogen or progesterone administration, or with pregnancy. One patient had a superficial spreading melanoma removed at the age of 13 yr and had no evidence of metastasis until 8 mo after she began taking an anovulatory drug at the age of 19 yr. Another patient developed melanoma in a nevus of Ota 2 yr after commencing oral contraceptive use. The third patient developed ulceration and bleeding of a nevus with subsequent metastasis in association with pregnancy. (4 refs)

79-5673 Carcinogenic Activity of 2-Aminoacetophenone in Syrian Hamsters. (Rus) Khar'kovskaia, N. A. (Dept. Lab. Animals, Cancer Res. Center, Moscow, USSR). *Vopr Onkol* 25(6): 81-84; 1979.

The carcinogenicity of 2-aminoacetophenone (2-AAP: 10 mg sc 2x/wk for 10 wk) was studied in Syrian hamsters. 2-AAP increased the incidence of tumors: 23/39 treated hamsters developed tumors,

compared with 33/95 controls. Of 23 tumor-bearing treated hamsters, 18 had tumors of the endocrine system (14/18 were tumors of the adrenal cortex), but only 19/33 tumor-bearing control hamsters had spontaneous tumors of the endocrine system (16/19 were tumors of the adrenal cortex). 2-AAP also induced an adenoma in the medullary layer of the adrenal, granulocellular ovarian tumor, a seminoma, a squamous cell lung carcinoma, and a urinary bladder carcinoma. (4 refs)

79-5674 Gossypol-Proposed Contraceptive for Men Passes the Ames Test (Letter to Editor). (Eng) de Peyster, A. (Univ. California Sch. Public Health, Berkeley, CA 94720); Wang, Y. Y. *N Engl J Med* 301(5): 275-276; 1979.

The results of two separate mutagenicity assays of gossypol using the Ames salmonella-microsome test indicated that the new contraceptive is not mutagenic to the five standard tester strains of *S. typhimurium*, either with or without inclusion of a rat liver metabolic-enzyme fraction (S9). PHYSICAL CARCINOGENESIS

79-5675 In Vitro Comparison of Normal and Trisomic Cell Sensitivity to Physical and Chemical Mutagens. (Eng) Kucerova, M. (Genetics Lab., Inst. Hygiene and Epidemiology, Srobarova 48, 10042 Prague 10, Czechoslovakia); Polikova, Z. In: *Mutagen-induced Chromosome Damage in Man. Proceedings of a Symposium held in Edinburgh, Scotland, July 7-8, 1977*. Medical Research Council (Edinburgh, Scotland): 355 pp.; 185-190; 1978.

The in vitro sensitivity of normal and trisomic cells to radiation was compared, along with the sensitivity of these cells to mitomycin C. Lymphocytes from four healthy male donors and from four males with Down's syndrome were irradiated with 100, 200, 300 or 400 rads of x-rays or exposed to 10^{-4} to 10^{-6} mg/ml mitomycin C. The numbers and types of chromosome aberrations were analyzed by the conventional technique, and the yield of sister-chromatid exchanges (SCE's) was scored by the fluorescence plus Giemsa technique. As expected, the radiosensitivity of trisomic cells, measured by the number of chromosome aberrations, was higher than that of normal cells. The number of SCE's in both types of cells exposed to 100 rads was not significantly changed in comparison with controls. The sensitivity of trisomic and normal cells to mitomycin C appeared to be similar. The frequency of aberrations and SCE's in both types of cells was dependent on the concentration of the drug. (7 refs)

79-5676 Metabolism of Nucleic Acids in Radiosensitive Tissues of Rats after Single Administration of Tritium Hydroxide. (Rus) Shorokhova, V. B. (No affiliation given); Revina, V. S.; Turdakova, V. A.; Mushkacheva, G. S. *Radiobiologiya* 19(3): 323-329; 1979.

The immediate and long-term effects of a single po dose of tritium hydroxide (T-OH: 0.6 mCi/g) were studied in male Wistar rats. Animals were sacrificed at different times after exposure, and the rate of synthesis of nucleic acids in the bone marrow, spleen, and thymus was determined. T-OH decreased the life-span of the rats by 40% (419 days, compared with 699 days in controls) and increased the incidence of tumors: 11.8% had connective tissue tumors (vs 1.2% in controls), 8.9% had mammary gland tumors (vs 2.3%), 10.8% had lung tumors (vs 3.4%), 1.9% had kidney tumors (vs 0%), 3.9% had bone tumors (vs 0%), and 2.9% had leukemias (vs 3.4%). The duration of survival of the tumor-bearing rats was 454 days, compared with 606 days for tumor-bearing rats that were not treated with T-OH. Analysis of the level and rate of nucleic acid synthesis revealed that there was a marked decrease in the concentration of DNA in radiosensitive tissues: on days 3-7 of exposure, there was a 30%-40% decrease of the DNA level in the bone marrow and thymus and a 60% decrease in the spleen. Starting on day 14 of exposure, DNA levels showed a tendency toward normalization, but later there was a second 25%-30% decrease of DNA levels in the bone marrow and spleen (12 mo after exposure) and an approx 50% decrease in the thymus (6 and 12 mo after exposure). 79-5677 Dynamics of Changes in Connective Tissue of Rats During Ethacryl (AKP-15)-induced Tumorigenesis.

(Rus) Eliseev, V. V. (Lab. Chemical Carcinogens, N. N. Petrov Res. Inst. Oncology, Leningrad, USSR). *Vopr Onkol* 25(6): 65-69; 1979.

The effect of the implantation of plastic Ethacryl (AKP-15) plates was studied in random-bred albino rats. Plates measuring 20 x 20 x 1 mm were implanted sc, and the animals were followed for 1-16 mo. A connective tissue capsule that was composed of three layers was formed by the end of the first month of implantation. Proliferative activity began to subside 3 mo after implantation, but 6 mo after implantation, some capsules contained foci of diffuse proliferation in the internal layer. These foci consisted of immature fibroblasts without signs of cellular atypia. Foci of atypical cells were first detected by 10-11 mo after implantation. Progressive replacement of the capsule tissue was followed by the formation of a tumor nodule. (10 refs)

79-5678 Competitive Radiation-induced Carcinogenesis: An Analysis of Data from Beagle Dogs Exposed to ^{226}Ra and ^{90}Sr . (Eng) Momeni, M. H. (Div. Environmental Impact Studies, Argonne Natl. Lab., Argonne, IL 60439). *Health Phys* 36(3): 295-310; 1979.

The incidence of radiation-induced primary bone sarcoma and myeloproliferative disease was studied as a function of dose rate and time in 776 beagles. The dogs were fed diets containing $^{90}\text{SrCl}_2$ in equilibrium with ^{90}Y from midgestation to 1.5 yr of age or they were given eight iv injections of $^{226}\text{RaCl}_2$ (one injection every 2 wk for 4 mo) starting at 14 mo of age. Analysis of the incidence of each disease in the beagles showed a normal probability density function with respect to time. Median incidence time and standard deviation from the mean of distribution were calculated for primary osteosarcoma at each level of administered radioactivity. The median incidence age (T) for mortality from primary osteosarcoma increased from 4.1 yr, 2.6 yr after the final radium injection, for beagles injected (A_0) with 83.6 μCi ^{226}Ra , to 11.5 yr for beagles given $A_0 = 3.14 \mu\text{Ci}$ ^{226}Ra . For beagles that ingested a daily diet containing $^{90}\text{Sr} + ^{90}\text{Y}$, from T increased 2.8 yr at 36 μCi ^{90}Sr /day to 12.6 yr at 4 μCi ^{90}Sr /day. Tumor yield was calculated assuming that the causes of death from competing diseases were mutually exclusive with respect to individual diseases. Incidence and cumulative incidence for each of the diseases were calculated as a function of time and max dose rate. These analyses were extended to beagles administered ^{226}Ra by a single injection or ^{90}Sr by injection and inhalation. Extrapolation of the observed dose effects to lower levels of administered radioactivity (comparable to max permissible body burden) is discussed within the frame of a competitive mortality from factors unrelated to radiation. (48 refs)

79-5679 Cytogenetic Investigation of People in Finland Using Household Water with High Natural Radioactivity. (Eng) Stenstrand, K. (Inst. Radiation Protection, Box 268, SE-00101 Helsinki 10, Finland); Annanmaki, M.; Rytomaa, T. *Health Phys* 36(3): 441-444; 1979.

Peripheral lymphocytes obtained from 18 individuals (aged 13-74

yr) living in five different dwellings where the household water has high natural radioactivity (^{222}Rn) were examined for frequency of chromosome aberrations. Nine men (aged 23-45 yr) served as controls. Slides prepared from 48-hr harvests were scored for the prevalence of dicentrics, centric rings, and acentrics. A total of 6,752 cells from the exposed group were analyzed, and 42 showed chromosome aberrations (18 dicentrics, 1 centric ring, 34 acentrics); 14/4,520 cells from the control group showed chromosome aberrations (1 dicentric, 1 centric ring, 12 acentrics). The total number of chromosome aberrations and the frequency of breaks resulting in dicentrics were significantly higher ($P < 0.001$) in the exposed group. (15 refs)

- 79-5680** An Investigation of UV-induced Chromosome Changes in Relation to Lethality in Normal and UV-sensitive Human Cells. (Eng) Scott, D. (Paterson Labs., Christie Hosp., Manchester M20 9BX, England); Marshall, R. R. In: *Mutagen-induced Chromosome Damage in Man. Proceedings of a Symposium held in Edinburgh, Scotland, July 7-8, 1977.* Medical Research Council (Edinburgh, Scotland): 355 pp.; 129-141; 1978.

The role of chromosome (CS) damage in UV-induced cell lethality and other mechanisms of cell death were investigated, and cytogenetic studies were carried out in normal and UV-sensitive human cells. CS structural aberrations, chiefly chromatid deletions and a few exchanges, were more frequent in xeroderma pigmentosum XP25RO cells than in normal 1BR cells following UV irradiation [0.5 or 1.0 joule (J/m^2)]. The only effect of the lower UV dose on cell-cycle times was to increase the S phase in XP25RO cells from 7.75 to 10.25 hr. A comparison of the labeled mitosis curves with those for metaphase aberration frequencies after the lower UV dose indicated that the aberrations were mainly in first division 1BR cells and in second- and third-division XP25RO cells. Only aberrations that affect both daughter cells and that arise during the first division can have a significant effect on colony-forming ability; hence, the frequency of these aberrations (3.3%) in UV-irradiated XP25RO cells is too small to account for the degree of cell killing (87%). Moreover, interphase death (occurring in 20% of postirradiation XP25RO cells) in combination with a 4% CS aberration frequency in both daughter cells from cells (80%) that do undergo their first mitosis can account for only about 23% of cell death. The death of UV-irradiated XP25RO cells, occurs mainly after their second division. Only occasional anaphase fragments and no CS bridges or multipolar divisions were seen in 1BR or XP25RO cells exposed to 0.5 J/m^2 UV light. Metaphase CS structural aberrations were not increased above control levels in 1BR cells or 11961 cells (from a UV-sensitive individual without detectable DNA repair defects) exposed to 1.5 J/m^2 UV light, although this dose killed approx 20% and 90% of the cells, respectively. A few bridges and anaphase fragments but virtually no multipolar mitoses were observed in these cells, either in control or irradiated populations. UV radiation did not markedly increase the frequency of sister chromatid exchanges (SCE's) in 11961 cells, and the spontaneous frequency of SCE's in these cells was a little higher than that in 1BR cells. Hence, cell death due to UV irradiation cannot be attributed to an increased frequency of SCE's. It is concluded that conventional CS structural aberrations play little or no role in UV-induced cell lethality. (25 refs)

- 79-5681** A Cytogenetic Study of Hiroshima Atomic-Bomb Survivors. (Eng) Sofuni, T. (Cytogenetics Section, Dept. Clinical Labs., Radiation Effects Res. Foundation, 5-2 Hi-

jiyama Park, Hiroshima 730, Japan); Shimba, H.; Ohtaki, K.; Awa, A. A. In: *Mutagen-induced Chromosome Damage in Man. Proceedings of a Symposium held in Edinburgh, Scotland, July 7-8, 1977.* Medical Research Council (Edinburgh, Scotland): 355 pp.; 108-114; 1978.

A total of 896 metaphases from 2-day cultures of peripheral blood lymphocytes from 23 heavily exposed Hiroshima A-bomb survivors were examined first after conventional staining, then reexamined after trypsin G-band staining. The frequencies of cells with radiation-induced chromosome aberrations, mainly of the symmetric type, were compared for the two methods. Abnormal karyotypes were detected in 348 metaphases by either one or both methods. Of these aberrant cells, 293 were found to have chromosome aberrations by the conventional stain. There were 55 metaphases in which abnormalities were detected only by G-banding. Six cells were identified as abnormal by the ordinary stain but as normal by G-banding; four of these were misidentified in the ordinary preparation due to the presence of partially distorted chromosomes. Further G-banding analysis identified various exchanges, including several types of insertions and paracentric inversions, which could not be detected by the conventional technique. (10 refs)

- 79-5682** The Influence of DTPA on the Metabolism of Inhaled $^{239}\text{PuF}_4$ in Beagles. (Eng) McDonald, K. E. (Biology Dept., Pacific Northwest Lab., Richland, WA 99352); Dilley, J. V.; Sanders, C. L.; Mahaffey, J. A. *Health Phys* 36(5): 632-635; 1979.

The metabolism and translocation of ^{239}Pu inhaled as a fluoride and the effectiveness of dicalcium trisodium diethylenetriamine-pentaacetic acid (DTPA) therapy for the removal of inhaled $^{239}\text{PuF}_4$ were investigated in beagle dogs. Three dogs were exposed to the dry aerosol of $^{239}\text{PuF}_4$ only, while 2 hr after exposure, three dogs were injected ip with 0.5 g DTPA diluted to 10 ml with normal saline. DTPA injections were given on days 1, 4, 7, 11, 16, 18, 23, 37, 44, 51, and 58. The whole-body burden was monitored by whole body counting. On day 85 postexposure the dogs were killed, and complete necropsies were performed. The initial body burden for all six dogs averaged $9.5 \pm 6.1 \mu\text{Ci}$, and the initial alveolar deposition for all dogs averaged $1.3 \pm 0.7 \mu\text{Ci}$. The only significant difference in the $^{239}\text{PuF}_4$ content in organs was obtained in the liver: dogs treated with DTPA averaged 0.0048% while those not treated averaged 0.1%. This difference was considered insignificant since the amount of ^{239}Pu in the liver was small in both groups. One dog, for unknown reasons, excreted a great deal more plutonium than the other five dogs. When this dog was excluded, plutonium urinary excretion was higher in treated animals, but this increase was not statistically significant. It was concluded that $^{239}\text{PuF}_4$ in the lung is unresponsive to DTPA chelation therapy. (3 refs)

- 79-5683** Estimation of Long-Term Biological Elimination of Insoluble ^{192}Ir from the Human Lung. (Eng) Cool, D. A. (Radiation Biology and Biophysics, Univ. Rochester Sch. Medicine and Dentistry, Rochester, NY 14642); Cool, W. S.; Brodsky, A.; Eadie, G. G. *Health Phys* 36(5): 629-632; 1979.

An opportunity to study the long-term retention/elimination pattern of insoluble ^{192}Ir in the human lung arose from an inhalation accident involving two subjects in which approx 2 Ci escaped undetected from a hot cell. Initial in vivo measurements taken ap-

prox 14 hr postexposure (PE) indicated a deposition of about 412 and 278 μCi in the lungs of Subjects 1 and 2, respectively. The second measurement at 33 hr PE showed that 53.6 and 16.3 μCi of the material remained in the lungs, respectively; the lost activity was accounted for by the activity measured in the first day's fecal sample. Between days 4 and 6 PE, the remaining lung burden decreased approx 6.6%/day for Subject 1 and 2.5%/day for Subject 2, and weekly fecal samples collected over the 2-yr study period indicated a total elimination rate consistent with a biological half-life of $>1,000$ days. Urine samples collected during this period had very low activity, indicating that elimination did not proceed through the circulatory system. Lung scans from 2 days to 6 mo PE showed patterns of relatively uniform deposition and retention of particulates throughout the pulmonary regions of both subjects. Starting 13 days PE, a standard chair whole-body counting technique with two scintillation detectors (1 adjacent to the chest and 1 approx 1 m from the subject) was used to measure radionuclide activity in the subjects. Regression analysis gave biological half-life values of 2,220 and 2,870 days with the detector adjacent to the chest and 982 and 714 days with the detector at a 1-m distance. The difference between the effective half-lives became increasingly significant over the 2-yr test period and could not be explained by statistical variation at the 95% confidence level. One possible explanation for the difference is the biological translocation of the material over time. (15 refs)

79-5684 Nasal Carcinomas in Beagles after Inhalation of Relatively Soluble Forms of Beta-emitting Radionuclides. (Eng) Benjamin, S. A. (Collaborative Radiological Health Lab., Coll. Veterinary Medicine and Biomedical Sciences, Colorado State Univ., Fort Collins, CO 80523); Boecker, B. B.; Cuddihy, R. G.; McClellan, R. O. *J Natl Cancer Inst* 63(1): 133-139; 1979.

At 12-14 mo of age, beagles were exposed by inhalation to relatively soluble forms of single beta-emitting radionuclides, and they are being observed over their life-spans to determine biologic hazards associated with nuclear power production. The dogs were exposed to graded activity levels of $^{91}\text{YCl}_3$, $^{144}\text{CeCl}_3$, or $^{90}\text{SrCl}_2$. With $^{91}\text{YCl}_3$ and $^{144}\text{CeCl}_3$, a significant radiation dose was delivered to the respiratory tract, liver, and skeleton. With $^{90}\text{SrCl}_2$, the dose was almost totally to the skeleton. Squamous cell carcinomas associated with the nasal cavity were the most frequently observed neoplasms in the $^{91}\text{YCl}_3$ study and one of the most frequent in the $^{144}\text{CeCl}_3$ study, whereas few squamous cell carcinomas were seen with $^{90}\text{SrCl}_2$. One nasal cavity hemangiosarcoma was also seen with ^{144}Ce . The incidence of nasal carcinomas may be related to higher relative concentrations of the radionuclides ^{91}Y and ^{144}Ce in the nasal turbinates. This relatively high risk of nasal cavity neoplasms suggests that standards for human exposure to these radionuclides should include a consideration of nasal cavity epithelium as a major target tissue. (29 refs)

79-5685 Effects of Low-Level X-Radiation on 7,12-Dimethylbenz(a)anthracene-induced Lingual Tumors in Syrian Golden Hamsters. (Eng) Lurie, A. G. (Dept. Oral Diagnosis-Oral Radiology, Univ. Connecticut Health Center, Sch. Dental Medicine, Farmington, CT 06032); Cutler, L. S. *J Natl Cancer Inst* 63(1): 147-152; 1979.

The effects of repeated low-level x-radiation of the head and neck on lingual tumor induction by 7,12-dimethylbenz(a)anthracene (DMBA) were studied in Syrian Golden hamsters. Animals received

either topical application of 0.5% DMBA in acetone on the lateral middle third of the tongue 3x/wk for 15 consecutive wk, 20-R x-radiation exposures to the head and neck once a week for 15 wk, or concurrent radiation and DMBA treatments for 15 wk. Animals were examined visually at regular intervals, and all were killed 35 wk after the start of treatments. All tissues were then examined histopathologically. Animals receiving radiation alone had no detectable changes. Animals receiving DMBA + radiation had an excess of papillomas compared with animals receiving only DMBA (35% vs 15%). In addition, an excess of nonlingual oral tumors (lip, gingiva, and floor of mouth) was found in DMBA + radiation-treated animals vs DMBA-treated animals. These results suggest that repeated, localized, low-level x-radiation enhances chemical tumorigenesis in a variety of oral tissues of Syrian golden hamsters. (14 refs)

79-5686 Plutonium in the Tissues of Foetal, Neonatal and Suckling Mice after Pu-Administration to Their Dams. (Eng) Green, D. (Medical Res. Council Radiobiology Unit, Harwell, Didcot, Oxfordshire, England); Howells, G. R.; Watts, R. H. *Int J Radiat Biol* 35(5): 417-432; 1979.

The uptake of plutonium-239 by the mouse fetus, membranes, and placenta during gestation and its distribution in the 1-day-old neonate and the 18-day-old suckling were determined. Twelve-wk-old female (C3H x 101)F₁ mice were injected iv with an ultrafiltered soln of ^{239}Pu in 1% trisodium citrate, and mated to uninjected PCT males. The Pu content was examined radiochemically and autoradiographically in the placenta and fetuses on gestation days 12 and 18, in neonates during the 24 hr after birth, and in sucklings 18 days postnatally. The distribution of Pu in most tissues of the late fetus and the suckling was similar to that in adult mice. However, on gestation days 12 and 18, the concentration in the yolk-sac splanchnopleura was much higher than that in any other fetal tissue. The amount of ^{239}Pu in 18-day-old sucklings was between two and seven times as great as that in 1-day-old neonates because of the ingestion of milk from lactating dams. In the first litter following administration of the radionuclide to the dam, about 0.02% of the Pu injected was transferred to each offspring by the time of birth and a further 0.08% was transferred by the time of weaning. 79-5687 Ionizing Radiation Perturbs the Switch-on of Transcriptase in a Model Transcription Complex In Vitro. (Eng) Borsa, J. (Medical Biophysics Branch, Whiteshell Nuclear Res. Establishment, Atomic Energy Canada Ltd., Pinawa, Manitoba ROE 1LO, Canada); Sargent, M. D.; Lievaart, P. A. *Int J Radiat Biol* 35(5): 459-472; 1979.

A model in vitro transcription complex derived from reovirus type 3 was used to study the effect of ionizing radiation on cellular functions. The model complex, the intermediate subviral particle (ISVP), is converted from a blocked [inactive transcriptase (TS)] to an unblocked (active TS) form by an endogenous switch mechanism triggered by the intracellular (physiological) K⁺ concentration. Intact virions, ISVP's and virus core particles were irradiated in a cobalt-60 gamma-ray chamber at 7.9 krad/min. Intact reovirions and ISVP's contain blocked endogenous TS; virus core particles contain unblocked endogenous TS. Irradiating intact virions failed to unblock TS activity; irradiating core particles inactivated TS activity with single-hit kinetics; and irradiating ISVP's unblocked TS activity in a dose-dependent manner: TS activity at first increased, passed through a max, and then decreased

to background levels. A synergistic interaction was demonstrated between ionizing radiation and K^+ concentration in effecting TS switch-on: (1) increasing doses of radiation lowered, in a dose-dependent fashion, the concentration of K^+ required to trigger switch-on; (2) radiation could not effect switch-on in the absence of K^+ , but increasing concentrations of K^+ increased the effectiveness of a given radiation dose to trigger switch-on. These results suggest that ionizing radiation stably alters the ISVP in some way, changing its response to K^+ stimulation. When the response of control and irradiated ISVPs to K^+ stimulation was compared in the presence of various perturbations (bentonite, chymotrypsin, Hg^{2+} , varying temperature), the two species were identical, indicating that the unblocking mechanism is identical in the two types of ISVP. The size distributions of product RNA synthesized by irradiated and unirradiated ISVP's were very similar, indicating that the K^+ -radiation-induced readout produces functional messenger RNA and that the decline in TS activity at high radiation doses is not due to premature termination of transcription. Biophysical characterization of irradiated and control ISVP's ruled out a loss of particle components or a change in their packing arrangement. However, in irradiated particles, the major polypeptide band δ , is split into two species upon electrophoresis. This change may account for the TS-unblocking effect of radiation on ISVP's. - 79-5688 Photoreactivation of Ionizing-Radiation-induced Damage in *E. coli*. Influence of Chemical and Physical Factors. (Eng) Redpath, J. L. (Div. Radiation Oncology, Dept. Radiobiological Sciences, Univ. California, Irvine, CA 92717); Zabilansky, E. *Int J Radiat Biol* 35(5): 473-476; 1979.

Evidence is presented to support the hypothesis that photoreactivatable damage to DNA is the same whether produced by UV or ionizing radiation. *Escherichia coli* strains Bs-1 (*uvrBexrA*) and AB2480 (*uvrArecA*) were used; late log-phase cells were diluted to a concentration of 10^6 cells/ml, irradiated in the dark, and exposed to low-intensity room light or a high-intensity light source. Because caffeine inhibits the photoreactivation (PR) of UV-induced damage by competing with the PR enzyme for its substrate, the effect of caffeine on PR in Bs-1 cells treated with ionizing radiation was examined. Caffeine reduced the rate of PR in low-intensity light by a factor of about 4. Thus, the effect of caffeine on PR is similar whether the damage is induced by UV or by ionizing radiation. The effect of the radioprotective agent dithiothreitol (DTT) on the amount of photoreactivatable damage following a dose of ionizing radiation was examined. The presence of DTT during irradiation of Bs-1 or AB2480 cells did not reduce the amount of damage, indicating that the mechanism of irradiation damage is not likely to be mediated by free radicals. This finding favors a mechanism involving the production of an excited state in the target. The extent of PR in both Bs-1 and AB 2480 cells was measured following various doses of x-rays. The energy of the damage-inducing x-radiation influenced the extent of repair, with little or no PR being observed below a certain dose. The mechanism of this dependence is currently under investigation. (7 refs)

- 79-5689 Radiation Risk and Gonad Exposure from Diagnostic X-rays. (Ger) Vogel, H. (Abt. Röntgendiagnostik, Radiologischen Univ.-Klinik im Klinikum Hamburg-Eppendorf, Martinistrasse 52, D-2000 Hamburg 20, W. Germany). *Munch Med Wochenschr* 121(28): 943-946; 1979.

The risks of malignancy or mutation induction from low levels of radiation were calculated based on data from the International Council on Radiation Protection (ICRP: Report 26) and the author's own measurements. Radiation of one million persons with 1 rem (radiation-equivalent-man) is estimated to lead to 100 additional malformations caused by mutations in the next two generations; the spontaneous rate is 3%. Risks from special diagnostic tests were also calculated: one malformed child is to be expected from 41,000 infusion-urograms done on men during their reproductive years. Calculation of probabilities of malignancy-induction from radiation requires some simplifying assumptions. The dose-response curve is assumed to be linear in the region of interest, and dose-fractionation is ignored. The av organ dose is used for calculation. Risk of cancer death from exposure to 1 rem varies from 2×10^{-5} deaths from exposure of bone marrow or lung to 10^{-4} for whole-body or gonad exposure. Because the usual latent period for induction of malignancy is 7-30 yr, there is little risk for persons >80 yr old. Genetic risk does not exist for those beyond reproductive age. Genetic risk is lower for children before sexual maturation than for adults. Observable increases in genetic damage from the current level of diagnostic x-rays are not predicted by these calculations. (16 refs)

- 79-5690 Lung Cancer in Man in Relation to Different Time Distribution of Radiation Exposure. (Eng) Kunz, E. (Dept. Radiation Hygiene, Inst. Hygiene and Epidemiology, 100 42 Praha 10, Czechoslovakia); Sevc, J.; Placek, V.; Horacek, J. *Health Phys* 36(6): 699-706; 1979.

The relationship between lung cancer and duration of exposure to radiation was studied among a large group of uranium miners who were exposed to radon daughter products between 1948 and 1975. Except for adenocarcinoma, the frequency of all histologic types of lung cancer was elevated in the entire group, the small cell and epidermoid types being particularly frequent. The relationship between cumulative exposure and increased cancer frequency was linear throughout the entire course of exposure only among the men with the longest exposure times. The less-increased cancer frequencies among men with shorter exposure times was related to a relatively lower incidence of the small cell undifferentiated type of cancer. In one group of men, among whom exposures were initially low and then later increased, a significant decrease in the frequency of lung cancer in the highest exposure category was also due primarily to a decrease in the small cell undifferentiated type. - 79-5691 The Significance of Small Bowel Resistance to Tumor Growth: An Experimental Study. (Eng) Ortiz, V. N. (Div. Pediatric Surgery, Dept. Surgery, Ohio State Univ. Coll. Medicine, Columbus, OH 43205). *J Surg Res* 26(6): 693-697; 1979.

The mechanisms of the different patterns of bowel resistance to tumor growth were investigated using weanling and adult female Wistar rats and the Walker 256 carcinosarcoma. In adult rats sutured with material previously embedded in tumor fluid, tumor occurred in only 10% of ileoileal anastomoses, compared with 80%-90% of colocolic anastomoses and 30%-33% of ileocolostomies. Tumor growth to >1 cm in size occurred in 50% of the colocolostomies, 16% of the ileocolostomies, and none of the ileoileostomies. There was little difference in the flora of the animals at surgery or autopsy. Tumor growth occurred mainly in the submucosa at the suture line. In weanling rats implanted with

sutures previously treated with tumor fluid, tumor growth was observed in 60% of treated colons and only 10% of treated small bowels. In adults implanted sc with homogenates of large or small bowel mixed with tumor fluid, tumor growth was inhibited by the small bowel homogenate and unaffected by the large bowel homogenate or saline. The data indicate that the small bowel inhibits the growth of implanted tumor and that the inhibitory effect is in the wall of the small bowel. (3 refs)

- 79-5692 Psoralen-DNA Cross-linking Photoadducts in Dyskeratosis Congenita: Delay in Excision and Promotion of Sister Chromatid Exchange. (Eng) Carter, D. M. (Dept. Dermatology, Yale Univ. Sch. Medicine, New Haven, CT 06510); Pan, M.; Gaynor, A.; McGuire, J. S.; Sibrack, L. *J Invest Dermatol* 73(1): 97-101; 1979.

The responses of cultured fibroblasts and peripheral WBC from normal persons and two unrelated young adult men with dyskeratosis congenita (DC) were compared following exposure of the cells to 4,4',8-trimethylpsoralen (TMP) and UV light (UVL). DNA from DC cells exposed to TMP and UVL resembled DNA from normal cells with respect to patterns of sedimentation on alkaline sucrose gradients. DNA from treated cells sedimented more rapidly than that from untreated cells, and DNA from DC cells incubated for 24 hr in labeled medium after exposure to TMP and UVL still sedimented more rapidly than DNA from untreated cells. The number of sister-chromatid exchanges (SCE's) increased in WBC from normal persons and DC patients after exposure to TMP and UVL, the increase being dose-dependent in the case of the DC cells. The increase in SCE's was consistently greater for DC than for similarly treated normal cells. Treatment with psoralen or UVL alone did not affect SCE rates in DC cells. SCE values in the cells from a clinically normal brother of one DC patient resembled those from normal cells after TMP and UVL treatment, whereas the SCE values from the patient's mother were intermediate between the normal and DC values. The data are consistent with the concept that a defect in the ability to repair DNA cross-links is a fundamental abnormality in DC. (32 refs)

- 79-5693 Establishment and Characterization of C-Type RNA Virus-producing Cell Lines from Radiation-induced Murine Osteosarcomas. (Eng) Erfle, V. (Gesellschaft für Strahlen- und Umweltforschung mbH München, Institut für Biologie, D-8042 Neuherberg, W. Germany); Schulte-Overberg, S.; Marquart, K. H.; Adler, I. D.; Luz, A. *J Cancer Res Clin Oncol* 94(2): 149-162; 1979.

Eight cell lines established from murine osteosarcomas induced in vivo with the radionuclides ^{224}Ra and ^{227}Th were compared with respect to ultrastructure, karyotype, and growth properties. All cultures showed spindle-shaped cells, often in the form of cell clusters that tended to pile up. Criss-crossing was common, and pleomorphic polygonal and multinucleated giant cells were also seen. Chromosome studies revealed only mouse chromosomes with diploidy in six lines and hypotetraploidy in two. Karyotypes of the cells of four lines suggested a monoclonal origin of the cultures. Plating efficiencies, doubling times, growth in soft agar, and tumorigenicity in newborn and adult syngeneic mice indicated that five of the lines were tumor cell lines. All five cell lines contained marker chromosomes. The osteosarcoma cells of the tumor cell lines released particles into the medium that had typical properties of RNA tumor viruses: they possessed a C-type morphology, a density of 1.16-1.19 g/cm³, a 60S-70S RNA, and an

RNA-dependent DNA polymerase, and they induced syncytia in rat XC cells. (33 refs)

- 79-5694 Determination of the Uranium Content in Some Indian Cigarettes. (Eng) Chakarvarti, S. K. (Dept. Applied Physics, Regional Engineering Coll., Kurukshetra 132119, India); Dhiman, J.; Nagpaul, K. K. *Health Phys* 36(5): 638-640; 1979.

The average total uranium content of tobacco from 20 brands of Indian cigarettes as determined by a particle track etch technique was 0.04-0.1 µg/g. (9 refs)

- 79-5695 Lung Cancer Arising in Scars from Previous Thoracic Trauma. (Ita) Chiarelli, P. (Servizio di Radiologia, Ospedale Generale Provinciale, Via S. Fermo 1, 35042 Este, Padua, Italy); Carrara, M. *Radiol Med (Torino)* 65(4): 235-240; 1979.

Among a series of 60 patients with lung carcinoma, 13 had suffered previous thoracic trauma with or without rib fractures. This finding lends support to the theory that scar tissue may predispose to the development of carcinoma. (12 refs)

- 79-5696 Hepatoblastoma in a 36-Week Fetus. (Ita) Rua, S. (Servizio di anatomia ed istologia patologica, Ospedale Civile S. Croce di Cuneo, Cuneo, Italy); Olivieri, P.; Vucusa, C. *Pathologica* 71(1012): 273-278; 1979.

A hepatoblastoma was discovered in a fetus that died during the 36th wk of pregnancy. The mother had undergone x-ray examination of the abdomen and gallbladder on the 23rd day of pregnancy. She was not aware of her pregnancy at that time. The radiation and the contrast medium used for the cholecystography may have been involved in the etiology of this tumor. (29 refs)

- 79-5697 A Metabolic Model for Polonium. (Eng) Bernard, S. R. (Health and Safety Res. Div., Oak Ridge Natl. Lab., Oak Ridge, TN 37830). *Health Phys* 36(6): 731-732; 1979.

A polonium metabolic model for use in internal dose estimation work was developed using previously reported animal experimental data on ^{210}Po and human excretion data. (6 refs)

VIRAL CARCINOGENESIS

- 79-5698 Direct Method of Deriving Cultures of Chick Embryo Cells Not Producing the Group-specific Antigen of Avian Leukemia Viruses. (Rus) Shmel'kova, V. I. (Lab. Biochemistry, N. N. Petrov Res. Inst. Oncology, Leningrad, USSR); Kuznetsov, O. K.; Batrakova, V. P.; Fedorova, S. M.; Sokolova, A. N. *Vopr Onkol* 25(6): 125-126; 1979.

A direct method of assaying avian leukemia virus contamination in cultures of chicken embryo fibroblasts (CEF) is described. The assay consists of collecting blood samples from the embryo, preparing and then inactivating the sera, and testing the sera by a complement fixation reaction. Cultures of CEF were obtained that did not produce the group-specific antigen of avian leukosis viruses. The technique was significantly more effective than the conventional complement-fixation (COFAL) test. (5 refs)

- 79-5699 *Gs*, an Allele of Chickens for Endogenous Avian Leukosis Viral Antigens, Segregates with *ev* 3, a Genetic Locus That Contains Structural Genes for Virus. (Eng) Astrin, S. M. (Inst. Cancer Res., Fox Chase Cancer Center, Philadelphia, PA 19111); Robinson, H. L. *J Virol* 31(2): 420-425; 1979.

Gs is an allele of chickens for the expression of endogenous avian leukosis virus-related core (*gs*) and envelope (*chf*) antigens. Progeny of a genetic cross in which *Gs* was segregating were analyzed for endogenous viral DNA and for the expression of endogenous viral antigens. Viral genetic information was identified by the cleavage of embryo DNA with restriction endonucleases, electrophoretic separation of the resulting fragments, and identification of bands containing viral sequences by hybridization of the DNA to ³²P-labeled viral RNA. Four different chromosomal sites of residence of endogenous viral sequences were identified. These sites were the same as those previously assigned to the endogenous viral loci *ev* 1, *ev* 3, *ev* 4, and *ev* 5. *ev* 1 was present in all of the progeny of the cross. *ev* 3, *ev* 4, and *ev* 5 were present in various combinations with *ev* 1. *ev* 3 cosegregated with the *gs***chf** phenotype. Cells that did not contain *ev* 3 but contained *ev* 1, *ev* 4, and/or *ev* 5 did not express detectable levels of viral antigens. It is suggested that *gs* contains the structural genes for endogenous virus that reside at *ev* 3 and that these structural genes code for *gs* and *chf* in *gs***chf** cells. (31 refs)

- 79-5700 Chromatin Alterations and Gene Function Disorder in MC-29 Virus-derived Hepatoma. (Eng) Jeney, A. (First Inst. Pathology, Semmelweis Medical Univ., Budapest, Hungary); Kovalszky, I.; Gyapay, G.; Lapis, K.; Suba, Z. *J Toxicol Environ Health* 5(2/3): 509-516; 1979.

The effect of dexamethasone on DNA and RNA synthesis and the composition of chromatin was analyzed in MC-29 virus-derived transplantable hepatoma (VTH) in chickens. Dexamethasone was administered ip (1 mg/g body wt) for 6 hr. Nucleic acids were labeled during the final hr of dexamethasone treatment with [6-³H]-thymidine or [5-³H]-uridine. In VTH, DNA and RNA labeling were both higher after dexamethasone treatment: 56.6 ± 4.2 in

controls increased to 82.0 ± 11.8 in treated tumors for DNA; and 24.3 ± 3.9 in controls increased to 37.9 ± 6.2 in treated tumors for RNA. In normal chicken liver, DNA and RNA labeling decreased after dexamethasone treatment. Compared with the amounts in normal liver, acidic chromatin proteins designated as the 0.35 M NaCl soluble fraction and nonhistones were increased and the histones were decreased in VTH. A remarkable variation in the distribution pattern of nonhistones was observed with sodium dodecyl sulfate-polyacrylamide gel electrophoresis. When the amount of unique and repetitive DNA segments per cell was estimated, it was shown that the elevation in total DNA in VTH compared with normal liver results mainly from the repetitive segments, which increased by 200%, while the unique segments increased only 40%. It is shown that structural alteration of the receptor or chromatin components influencing the binding of regulatory molecules to DNA may be important in the damaged function of glucocorticoids in the VTH. The structural alterations of chromatin nonhistones may be responsible for the lack of physiological responses to steroids with VTH, and the increased proportion of repetitive DNA sequences may be a characteristic of the disorder of gene regulation in malignant cells. (11 refs)

- 79-5701 Histology and Ultrastructural Aspects of Virus-induced Primary Liver Cancer and Transplantable Hepatomas of Viral Origin in Chickens. (Eng) Lapis, K. (First Inst. Pathology, Semmelweis Medical Univ., Budapest, Hungary). *J Toxicol Environ Health* 5(2/3): 469-501; 1979.

The macroscopic, light microscopic, and electron microscopic features and biological properties of MC-29 leukosis virus-induced hepatocellular carcinomas in chickens are described. The tumors developed in noncirrhotic livers within a very short time and formed metastases. The various histological types of tumors observed were very similar to those of human tumors. The presence of C-type viruses, especially in the intercellular spaces and bile capillaries, and signs of virus production were evidenced in the tumors. There were also indications of virus production in the transplantable tumors, which had a take rate of >90% and grew equally well after sc, ip, or im inoculation. In 6%-8% of the tumor cells, cytoplasmic inclusion bodies composed of peculiar undulating membranous structures appeared. Tumorous nodules developed in the liver of about 25% of the tumor-bearing animals. It could not be established whether they were metastases or primary liver cancers induced by viruses released from the transplantable tumors. (137 refs)

- 79-5702 Comparative Study of Tumor-specific Transplantation Antigens of MC-29 Chicken Hepatoma and Rous Sarcoma Virus-induced Sarcomas in Mice. (Eng) Elek, G. (First Inst. Pathology, Semmelweis Univ., Budapest, Hungary); Lapis, K.; Foldes, I. *J Toxicol Environ Health* 5(2/3): 529-536; 1979.

The take rate and growth of transplantable sarcomas induced by Rous sarcoma virus, Schmidt-Ruppin strain [RSV(SR)], were analyzed in syngeneic mice immunized with antigen prepared from a MC-29 virus-induced chicken hepatoma and in control syngeneic

mice. Immunization of CBAT6T6 mice with chicken MC-29 hepatoma antigen did not change the number of takes of RSV(SR) tumors after sc transplantation. Immunization only slightly increased the av survival time of the mice, and it significantly decreased tumor growth only at the minimum lethal dose level. Immunization of mice with MC-29 hepatoma antigen and with chicken Rous sarcoma antigen gave similar results; both elicited much less transplantation resistance than immunization with irradiated RSV(SR) tumor cells. The data indicate that there are common tumor-specific transplantation antigens of MC-29 hepatoma and Rous sarcoma, but further in vitro experiments are needed to prove this. (23 refs)

- 79-5703 Biochemical Behavior of MC-29 Virus-induced Transplantable Chicken Hepatoma. (Eng) Prajda, N. (Natl. Inst. Oncology, Budapest, Hungary); Eckhardt, S.; Suba, Z.; Lapis, K. *J Toxicol Environ Health* 5(2/3): 503-508; 1979.

The applicability of the molecular correlation concept developed for chemically induced transplantable rat hepatomas to virally induced transplantable hepatomas in chickens was tested. In the experimental group, transplantable MC-29 virus-induced hepatomas were maintained in Hunnia hybrid chickens for 10 days. The animals were decapitated, their livers and hepatomas were homogenized, and protein content and enzyme contents were analyzed. The following enzymes were assayed: hexokinase (HK), pyruvate kinase (PK), glucose-6-phosphatase (G6P), glucose-6-phosphate dehydrogenase (G6PDH), thymidine kinase (TK), glutamine phosphoribosylpyrophosphate amidotransferase (G-PRPP-AT) and xanthine oxidase (XO). When compared with enzyme activities in the rat, the chicken liver enzymes were as follows: HK, 133%; PK, 88%; G6P, 175%; G6PDH, 25%; TK, 277%; G-PRPP-AT, 1,355%; and XO, 29%. In chemically and virally induced rapidly growing hepatomas, the pattern of neoplastic alterations was similar: the activities of the glycolytic enzymes were increased and those of the gluconeogenic enzyme were decreased in both tumors. In both types of tumor the increases in the activities of G6PDH and TK were observed; G-PRPP-AT activity increased, while that of XO decreased. In the hepatoma, the enzymatic imbalance was completely different from the pattern in differentiating liver and thus seems to be specific for the neoplastic transformation. (14 refs)

- 79-5704 Influence of Immune Status on Virus-Derived Transplantable Hepatoma in Chickens. (Eng) Foldes, I. (Microbiological Res. Group, Hungarian Acad. Sciences, Budapest, Hungary). *J Toxicol Environ Health* 5(2/3): 517-528; 1979.

The transplantable MC-29 virus-induced chicken hepatoma was used as an experimental model to investigate the effect of immune status on virus-derived transplantable hepatoma. Surgical bursectomy and thymectomy were performed on groups of Hunnia hybrid or White Leghorn chickens; then tumor homogenate was transplanted on the same day, or 7 or 14 days thereafter. No differences in tumor take were observed when the tumor was transplanted on the day of hatching. When the transplantation occurred on day 7 after hatching, the thymectomized birds succumbed earlier. When tumors were transplanted on day 14, bursectomy and thymectomy increased the frequency of tumor take. Tumorigenesis could not be influenced by the adoptive transfer of immune serum and immune cells in this tumor system. Tumor growth was inhibited but not prevented by the administration of

live BCG or strain W-115 of *Mycobacterium tuberculosis* together with the tumor transplant. When the hepatoma was transplanted into newly hatched chickens and the birds were killed 10 or 14 days thereafter, the weight of the bursa of Fabricius and the thymus decreased in the tumor-bearing animals; and a marked decrease in the thymus cells was observed. In normal birds, dexamethasone markedly induced hepatic tyrosine aminotransferase (TAT), while no detectable change was observed in tumor-bearing birds. This difference indicates that the mechanism of control of protein synthesis was impaired in the early phase of tumor development. Glucagon increased the TAT activity in both normal and tumor-bearing chickens. When glucocorticoid hormones were administered twice in 48 hr, an 80% decrease in thymidine kinase activity was observed in the thymus lobes of healthy chickens, while no response was observed in the tumor-bearing chickens. In cell-free systems prepared from thymus lobes of tumor-bearing chickens, a significant decrease in the steroid binding capacity was observed. (12 refs)

- 79-5705 DNA Endonucleases Associated with the Avian Myeloblastosis Virus DNA Polymerase. (Eng) Samuel, K. P. (Dept. Human Genetics and Development, Coll. Physicians and Surgeons, Columbia Univ., 630 W. 168 St., New York, NY 10032); Papas, T. S.; Chirikjian, J. G. *Proc Natl Acad Sci USA* 76(6): 2659-2663; 1979.

Two endonucleases that are present in avian myeloblastosis virus cores and use superhelical DNA's as substrates are described. DNA endonuclease Endo-I was isolated from avian myeloblastosis virions stripped of their coats by mild detergent treatment. The enzyme has a broad pH optimum around 7.5-8.0 and requires Mg^{2+} for activity. A second endonuclease, Endo-II, with a requirement for Mn^{2+} , was also present in the viral cores. It copurified with avian myeloblastosis virus $\alpha\beta$ DNA polymerase (reverse transcriptase, RNA-dependent DNA nucleotidyltransferase) and similarly cleaved superhelical DNA's. Heat denaturation and sodium fluoride- and N-ethylmaleimide inhibition studies were carried out to demonstrate a possible relationship between the two endonucleases and the viral DNA polymerase and RNase H activities. It appears that Endo-II may be an intrinsic activity of the polymerase. (24 refs)

- 79-5706 Stimulation of Sugar Uptake and Glycolysis in Chicken Embryo Fibroblasts by the Major Glycoprotein from Avian Myeloblastosis Virus. (Eng) Papamatheakis, J. D. (Lab. Tumor Virus Genetics, NCI, NIH, Bethesda, MD 20205); Marciani, D. J. *Proc Natl Acad Sci USA* 76(6): 2784-2788; 1979.

The occurrence of significant changes in glucose transport and glycolysis in normal chicken embryo fibroblasts (CEF) after treatment of these cells with the highly purified major glycoprotein (gp) from avian myeloblastosis virus (AMV) is reported. Addition of the gp to growing or quiescent CEF rapidly stimulated the rate of hexose transport and increased lactic acid production. These stimulatory effects were dependent on the time of exposure and the dose of viral gp. In contrast, the gp only marginally affected hexose transport in chicken cells transformed by Rous sarcoma virus. Some effects of the gp on serum-starved quiescent cells were similar to those observed upon readdition of serum; however, the viral gp did not stimulate DNA synthesis. Quiescent cells stimulated by saturating levels of serum showed little further stimulation of hexose uptake upon exposure to viral gp for 3 hr. This behavior suggests that the gp may be acting on a system that is also a target for serum action. (21 refs)

- 79-5707 Cellular Information in the Genome of Recovered Avian Sarcoma Virus Directs the Synthesis of Transforming Protein. (Eng) Karess, R. E. (Rockefeller Univ., New York, NY 10021); Hayward, W. S.; Hanafusa, H. *Proc Natl Acad Sci USA* 76(7): 3154-3158; 1979.

The presence of information directing the production of transforming protein (p60^{src}) in avian sarcoma viruses (rASV's) recovered from chicken tumors was investigated. Immunoprecipitation of chicken embryo fibroblasts infected with different rASV's with serum raised in rabbits bearing regressing tumors induced by the Schmidt-Ruppin strain of ASV, subgroup D (SR-D), revealed that a protein migrated with the p60^{src} of subgroup A virus (SR-A). The p60^{src} from rASV was a phosphoprotein. The p60^{src} from cells infected with different rASV's and the p60^{src} from normal cells showed nearly identical proteolytic digestion patterns. Immunoprecipitates of p60^{src} from rASV-infected cells possessed protein kinase activity. The amounts of p60^{src} obtained from cells transformed with rASV 1441 or SR-A were similar, whereas the amount recovered from untransformed cells was 100- to 200-fold less. The amounts of *src*-specific messenger RNA's were correlated with the amounts of p60^{src} and p60^{src} in transformed and normal cells. (30 refs)

- 79-5708 Transformation of NIH/3T3 Mouse Cells by DNA of Rous Sarcoma Virus. (Eng) Copeland, N. G. (Dept. Pathology, Harvard Medical Sch., Boston, MA 02115); Zelenetz, A. D.; Cooper, G. M. *Cell* 17(4): 993-1002; 1979.

To determine whether previously observed differences in the mechanisms of transfection of chicken cells by Rous sarcoma virus (RSV) DNA and of mouse cells by murine sarcoma virus (MSV) DNA were due to differences in the recipient cells or to differences in the virus DNAs, transformation of NIH/3T3 mouse cells by RSV DNA was investigated. The mouse cells were transformed by integrated and unintegrated DNAs of RSV-infected chicken cells without production of progeny virus. In addition, DNA of the replication-defective Bryan high titer strain of RSV transformed NIH/3T3 cells, indicating that transformation of NIH/3T3 cells by RSV DNA did not require virus replication. The efficiency of transformation of NIH/3T3 cells by RSV DNA was similar to the efficiency of transformation of these cells by murine sarcoma virus DNA and to the efficiency of transfection of chicken embryo fibroblasts by RSV DNA. NIH/3T3 cells transformed by RSV DNA were morphologically similar to cells transformed by virus infection and were capable of anchorage-independent growth in soft agar. Stable inheritance of intact RSV genomes by RSV DNA-transformed NIH/3T3 cells were demonstrated by rescue of virus from these cells after fusion with chicken embryo fibroblasts and by transfection assays of the DNAs of RSV DNA-transformed NIH/3T3 cells on chicken embryo fibroblasts. Analysis of the DNAs of RSV DNA-transformed NIH/3T3 cells by restriction endonuclease digestion and nucleic acid hybridization indicated that RSV genomes were linked to cellular DNA sequences. It therefore appeared that transformation of NIH/3T3 cells by RSV DNA occurred by direct integration and stable expression of the donor DNA, rather than by production of extracellular progeny virus and secondary virus infection. - 79-5709 Analysis of the Specificity of Integration of Provirus DNA of Rous Sarcoma Virus into DNA of Transformed Rat Cells. (Rus) Farashian, V. R. (D. I. Ivanovskii Inst. Virology, Moscow, USSR); Gudkov, A. V.; Naroditskii, B.

S.; Obukh, I. B.; Tikhonenko, T. I.; Zhdanov, V. M. *Dokl Akad Nauk SSSR* 247(4): 967-970; 1979.

An attempt was made to determine the localization of virus-specific sequences of Rous sarcoma virus (RSV) in the DNA of transformed rat cells (DNA_{xc}). The XC cell line was derived from rat tumor induced by RSV (Prague strain, substrain C). DNA_{xc} hydrolysis using a series of endonucleases (R x *EcoRI*, R x *SalI*, R x *BamHI*) revealed a number of fragments with mol wt ranging from 0.5 to 20 megadaltons. It was suggested that the low mol wt fragments (0.6 and 0.9 megadaltons) correspond to internal regions of the provirus, while the group of fragments with mol wt ranging from 2.9 to 9 megadaltons may correspond either to the terminal fragments of provirus DNA combined with various cellular sequences, or to several proviruses that are tandemly incorporated into DNA_{xc}, or to several defective proviruses with deletions of various sizes. (15 refs)

- 79-5710 Suppression of Multiplication of Avian Sarcoma Virus by Rapid Spread of Transformation-defective Virus of the Same Subgroup. (Eng) Estis, L. F. (McArdle Lab. Cancer Res., Univ. Wisconsin, Madison, WI 53706); Temin, H. M. *J Virol* 31(2): 389-397; 1979.

A subgroup A avian sarcoma virus (ASV-A) that does not contain transformation-defective (*td*) virus and an independently isolated *td*ASV-A were used to test the hypothesis that some *td* viruses grow faster than the ASV's from which they are derived, resulting in establishment of interference by the *td* virus and suppression of ASV multiplication. At multiplicities of one or less in vitro, *td*ASV alone grew to higher titers and more rapidly than ASV alone. In mixed infections at low multiplicities that allowed the spread of progeny virus and with as little as 10% of the inoculum being *td* virus, there was an excess of *td* virus by 2 days after infection and a decrease in the titer of ASV relative to a control infection with no *td* virus. In mixed infections at high multiplicities that minimized the spread of progeny virus, there was no excess of *td* virus and the ASV titer was not decreased relative to the control infection. There was no simple correlation between the amounts of unintegrated viral DNA early after infection and the titers of virus produced, indicating perhaps that virus production was determined by integrated viral DNA. The data support the proposed hypothesis and indicate that deletions in the ASV *src* gene may not be a high-frequency event. (26 refs)

- 79-5711 Hybridization Analysis of Viral Nucleotide Sequences in the DNA of Hamster Rous Sarcoma. (Rus) Ratovitskii, E. A. (Lab. Biochemistry, N. N. Petrov Res. Inst. Oncology, Leningrad, USSR); Shaposhnikov, Ia. D.; Korobitsin, L. P.; Gaber, V. K.; Blank, M. A.; Neishtadt, E. L. *Vopr Onkol* 25(6): 52-54; 1979.

An attempt was made to determine whether the DNA of hamster Rous sarcomas (induced by inoculation of hamsters with suspensions of chicken Rous sarcoma cells) contains the nucleotide sequence of virus RNA. Inoculation of chicks with a suspension of hamster tumor cells failed to induce tumors, which indicates that the hamster tumor does not produce Rous sarcoma virions. On the other hand, the hamster sarcoma cells contained the group-specific antigen of avian oncornavirus. Molecular hybridization of the viral RNA with DNA isolated from the hamster tumor cells showed that viral information was located in the region of moderately redundant and unique sequences of tumor DNA. (5 refs)

79-5712 Declining Procollagen mRNA Sequences in Chick Embryo Fibroblasts Infected with Rous Sarcoma Virus. (Eng) Sandmeyer, S. (Dept. Biochemistry, Univ. Washington, Seattle, WA 98195); Bornstein, P. *J Biol Chem* 254(12): 4950-4953; 1979.

The kinetics of the decrease in procollagen biosynthesis and in procollagen messenger RNA (mRNA) sequences during the first 84 hr after infection of chick embryo fibroblasts with Rous sarcoma virus (RSV) were investigated. Whether the initial reduction in procollagen synthesis could be attributed to the events which affect the concentration of the message or to factors altering the activity of the mRNA was studied. The time course of the decrease in procollagen biosynthesis was measured by sodium dodecyl sulfate-polyacrylamide gel electrophoresis and collagenase assay and compared with the decrease in procollagen mRNA sequences measured by hybridization to a complementary DNA (cDNA). Procollagen synthesis declined starting 24 hr after infection and continued to decline 84 hr after infection. In cells not infected with RSV procollagen synthesis increased during the same time period. After RSV infection a decline was observed in the procollagen sequences 24 hr postinfection and continued in parallel with the change in procollagen synthesis up to 84 hr. In uninfected cells, the level of procollagen mRNA levels increased significantly until 36 hr, when it reached a plateau and returned to initial levels by 84 hr. Electrophoresis of (2,3-³H)proline-labeled protein in chick embryo fibroblasts after RSV infection demonstrated a decrease in the density of the bands comigrating with pro α 1(I) and pro α 2 chains over the time course. At 48 hr postinfection, radioactivity in the two procollagen bands of the transformed cells was 43% of that in the control group. Transformed cell procollagen bands had decreased to 14% of the control value by 84 hr. Thus, even the initial decrease in procollagen biosynthesis was due to a decline in the level of procollagen mRNA. (28 refs)

79-5713 Mutants of Rous Sarcoma Virus with Extensive Deletions of the Viral Genome. (Eng) Martin, G. S. (Dept. Zoology, Univ. California, Berkeley, CA 94720); Radke, K.; Hughes, S.; Quintrell, N.; Bishop, J. M.; Varmus, H. E. *Virology* 96(2): 530-546; 1979.

Deletion mutants of Rous sarcoma virus (RSV) were isolated from a stock of Prague RSV that had been irradiated with UV light. Quail fibroblasts were infected with irradiated virus, and transformed clones were isolated by agar suspension culture. Three clones were obtained that did not release any virus particles. Analysis of DNA from these nonproducer clones with restriction endonucleases and the Southern DNA transfer technique indicated that the clones carry defective proviruses with deletions of approx 4×10^6 daltons of proviral DNA. The defective proviruses, which retain the viral transformation (*src*) gene, contain only $1.7\text{--}2.0 \times 10^6$ daltons of DNA. Multiple species of viral RNA containing sequences of the *src* gene were detected in these clones; some of these RNA's may contain both viral and cellular sequences. The protein product of the *src* gene, p60^{src}, was also synthesized in the nonproducer clones. However, these clones did not contain the products of the group-specific antigen (*gag*), DNA polymerase (*pol*), or envelope glycoprotein (*env*) genes, nor did they contain the 35S and 28S RNA species that are believed to represent the messengers for these viral gene products. The properties of these mutants indicate that expression of the *src* gene is sufficient for the induction of transformation. These clones may be useful in studies of the expression of this region of the genome. (44 refs)

79-5714 Studies of the Effect of Chloramphenicol, Ethidium Bromide and Camptothecin on the Reproduction of

Rous Sarcoma Virus in Infected Chick Embryo Cells. (Eng) Leblond-Larouche, L. (Institut du Cancer de Montreal, Centre Hospitalier Notre-Dame, Montreal, Quebec, Canada); Morais, R.; Zollinger, M. *J Gen Virol* 44(2): 323-331; 1979.

The effects of chloramphenicol (CAM), ethidium bromide (EB), and camptothecin (CN) on the reproduction of Rous sarcoma virus (RSV) in infected chick embryo fibroblasts (CEF) were studied to determine the role of mitochondria in RSV reproduction. In the presence of 80 $\mu\text{g/ml}$ CAM, the population doubling time of RSV-infected CEF increased initially, and then decreased significantly. EB (0.4 $\mu\text{g/ml}$) also decreased the cell growth rate, and CN (4.0 $\mu\text{g/ml}$) proved to be a potent inhibitor of cell division. Leucine, thymidine, and uridine incorporation into total cell macromolecules was unaffected by CAM, inhibited by 20%-44% by EB, and inhibited 35%-50% by CN. Mitochondrial translation in RSV-infected CEF was totally inhibited by 80 $\mu\text{g/ml}$ CAM, and labeled leucine incorporation into mitochondrial proteins was reduced. EB also inhibited the synthesis of proteins coded for by mitochondrial DNA (mDNA), whereas CN did not inhibit the incorporation of leucine and thymidine into mitochondrial proteins and mDNA, respectively. CAM and EB did not inhibit, and may have increased, virus production by RSV-infected cells, whereas CN did inhibit the production of infectious virus. The results indicate that the mitochondrial macromolecular synthetic machinery of RSV-infected CEF does not contribute to virus production. (40 refs)

79-5715 High-Frequency Recombination Within the *gag* Gene of Rous Sarcoma Virus. (Eng) Linial, M. (Div. Oncology, Fred Hutchinson Cancer Res. Center, Seattle, WA 98104); Brown, S. *J Virol* 31(1): 257-260; 1979.

Twenty-eight recombinants of Rous sarcoma virus were isolated 1 and 7 days after infection, selected for wild type in the *pol* and *src* genes, and analyzed for their *env* and *gag* phenotypes. A strong linkage between any two markers, including two within a single gene (*gag*), could not be shown. (20 refs)

79-5716 Use of Recombinant Plasmids to Characterize Collagen RNAs in Normal and Transformed Chick Embryo Fibroblasts. (Eng) Adams, S. L. (Lab. Molecular Biology, NCI, NIH, Bethesda, MD 20205); Alwine, J. C.; de Crombrughe, B.; Pastan, I. *J Biol Chem* 254(12): 4935-4938; 1979.

Two recombinant plasmids (pCOL1 and pCOL3) containing chick collagen DNA sequences were used to characterize messenger RNA's (mRNA's) for pro- α 1 (type 1) and pro- α 2 collagen, to identify two larger RNA species that contain pro- α 1 and pro- α 2 collagen RNA sequences, and to compare the amounts of these collagen-specific RNA's in normal chick embryo fibroblasts (CEF) and CEF transformed by Rous sarcoma virus. pCOL3 DNA retains only pro- α 1 collagen mRNA and pCOL1 DNA retains only pro- α 2 collagen mRNA. Poly(A)-containing RNA from chick embryo calvaria and long bones, tissues that are very active in collagen synthesis, were electrophoresed on agarose gels containing methylmercuric hydroxide and transferred to diazobenzyloxymethyl paper; these covalently bound RNA's were hybridized to ³²P-labeled pro- α 1 or pro- α 2 collagen DNA sequences derived from the recombinant plasmids. The pro- α 1 collagen probe identified two RNA's, a major species of 5,000 bases and a minor species of 7,100 bases. The pro- α 2 collagen probe hybridized to a major species very similar in size to the pro- α 1 mRNA, about

5,200 bases, and a minor species of 5,700 bases. It is possible that the 7,100- and 5,700-base RNA's represent precursors of pro- $\alpha 1$ and pro- $\alpha 2$ collagen mRNA, respectively. When similar hybridization experiments were performed with RNA from CEF, both the pro- $\alpha 1$ and pro- $\alpha 2$ collagen mRNA's were observed, as well as their corresponding larger species. With RNA's from CEF transformed by Rous sarcoma virus, however, the levels of all RNA species that hybridized with the pro- $\alpha 1$ and pro- $\alpha 2$ collagen DNA probes were significantly reduced. - 79-5717 New Procedure for Isolation of Rous Sarcoma Virus-specific RNA from Infected Cells. (Eng) Bromley, P. A. (Departement Biologie Moleculaire, Universite de Geneve, CH-1211 Geneva 4, Switzerland); Spahr, P. F.; Darlix, J. L. *J Virol* 31(1): 86-93; 1979.

The use of mercurated 'strong stop' complementary DNA (complementary to the 5'-terminal 101 nucleotides of Rous sarcoma virus RNA) in the isolation of virus-specific RNA from infected chicken embryo fibroblasts is described. Strong stop Rous sarcoma virus complementary DNA was mercurated chemically, and, as a result of the low complexity of this DNA, short hybridization times (up to 15 min) and heating in the absence of formamide were found to be adequate conditions for the isolation of virus-specific RNA. The purity of the isolated RNA was demonstrated by analysis of labeled RNase T1-resistant oligonucleotides by two-dimensional polyacrylamide gel electrophoresis. The isolated RNA could be translated in the in vitro protein synthesis system derived from rabbit reticulocytes, and an analysis of polypeptides programmed by isolated RNA before and after immunoprecipitation further demonstrated both the purity of the isolated messenger RNA and the quantitative nature of the isolation procedure. (28 refs)

- 79-5718 Endogenous Oncornaviral Antigen in the Bursa of Fabricius of 15B x 7₂ Chickens. (Eng) England, J. M. (Wistar Inst. Anatomy and Biology, 36th St. at Spruce, Philadelphia, PA 19104); Halpern, M. S. *Proc Natl Acad Sci USA* 76(6): 2908-2911; 1979.

Because infection of chickens with exogenous leukosis viruses specifically induces a B-cell lymphoma that arises in the bursa of Fabricius, the distribution of endogenous oncornaviral antigen in the bursas of 15B x 7₂ chickens was investigated. These chickens spontaneously produce high levels of Rous-associated virus type 0. Oncornaviral antigen was detected in the bursal epithelium and in a subpopulation of bursal follicular cells of the chickens. This antigen was present in the bursal epithelium at 11 days of embryogenesis and persisted there for at least 3 wk after hatching. The absence of detectable antigen in the intestinal epithelium contiguous to the bursal epithelium indicates that the accumulation of viral antigen is a specific property of the bursal epithelium. The observation of C-type particles in the intraepithelial spaces suggests that the viral antigen is synthesized and assembled into virions by the bursal epithelial cells. In embryonic bursas, viral antigen-positive cells radiated from the surface epithelium toward the central region of the follicles. In bursas from posthatch chickens, viral antigen-positive cells, including intrafollicular epithelial cells and cells resembling lymphocytes, were confined to the medullary region of the follicles. (21 refs)

- 79-5719 Isolation and Development of a Reticuloendotheliosis Virus-transformed Lymphoblastoid Cell Line from Chicken Spleen Cells. (Eng) Keller, L. H. (Dept. Veterinary and Animal Sciences, Univ. Massachusetts, Amherst, MA 01003); Rufner, R.; Sevoian, M. *Infect Immun* 25(2): 694-701; 1979.

The in vitro establishment and characterization of a T-strain reticuloendotheliosis virus (REV-T)-transformed lymphoblastoid cell line (TV-1) derived from the spleen of a moribund SPAFA chick infected with REV-T are reported. Splenic cultures grown at 41 C were maintained in suspension culture for >74 wk, the generation time having stabilized at approx 15 hr. The optimal density for growth was 5×10^5 to 1×10^6 cells/ml. Karyotype analysis of the cells indicated the presence of a female chromosome (ZW). C-type REV-T budding virions were observed in the region of the plasma membrane, and particles characteristic of REV-T were observed extracellularly. TV-1 cells and their culture supernatant produced lesions typical of REV-T infection after inoculation into 1-day- to 1-wk-old chicks. The LD₅₀ remained constant at $10^{4.337}$ from 9 to 24 wk and then dropped to $10^{3.124}$ after 31 wk. Cytotoxicity assays and fluorescent antibody tests indicated the presence of B-cell determinants on the TV-1 cell-surface membranes. (17 refs)

- 79-5720 Lymphoid Neoplasms in Chicken Flocks Free of Infection with Exogenous Avian Tumor Viruses. (Eng) Crittenden, L. B. (Regional Poultry Res. Lab., Agricultural Res., Science and Education Admin., U.S. Dept. Agriculture, 3606 East Mount Hope Road, E. Lansing, MI 48823); Witter, R. L.; Okazaki, W.; Neiman, P. E. *J Natl Cancer Inst* 63(1): 191-200; 1979.

The hypothesis that full or partial expression of Rous-associated virus type 0 (RAV-0) is responsible for the lymphoid neoplasms in chickens free of infection with exogenous avian tumor viruses was investigated. More than 4,500 breeding female chickens of nine inbred lines maintained under specific-pathogen-free conditions to approx 500 days of age were studied. Routine monitoring and special assays indicated that they were free of infection by exogenous leukosis-sarcoma and reticuloendotheliosis viruses. Some birds were maintained free of Marek's disease (MD) virus infection in plastic isolators; and others were maintained in conventional chicken houses and vaccinated with herpesvirus of turkeys to prevent MD lesions. Ten birds bearing lymphoid tumors were observed in two sublines of a line of chickens known to produce embryos that spontaneously produce the endogenous RAV-0. Four tumors were found in chickens of one subline maintained free of MD virus infection in isolators. These tumors did not involve the bursa, and they had some histologic features different from those typical of lymphoid leukosis (LL). Six tumors were found in chickens of the other subline that were vaccinated to prevent MD; these tumors involved the bursa and were typical of LL but not MD. These results suggest that two types of tumors may have been observed. The fact that DNA from both tumor types did not contain exogenous LL virus sequences confirms the virologic evidence that exogenous viruses were not involved. The fact that endogenous viral sequences were not increased in copy number suggests that RAV-0 did not directly induce the tumors. Two birds with tumors not involving the bursa were found alive, and transplantable lymphoid tumors were developed. These tumors were of T-cell rather than bursa cell origin, as would be expected of LL. These are the first reported lymphoid tumors observed in the absence of known exogenous tumor virus infection in chickens. The evidence suggests that RAV-0 did not play a primary role in the induction of these tumors. (62 refs)

- 79-5721 Recombination Between the Defective Component of an Acute Leukemia Virus and Rous Associated Virus 0, an Endogenous Virus of Chickens. (Eng) Tschlis, P. N. (Dept. Medicine, Tufts Univ. Sch. Medicine, Boston, MA 02111); Coffin, J. M. *Proc Natl Acad Sci USA* 76(6): 3001-3005; 1979.

The ability of the defective acute leukemia virus of chickens, MC-29, to participate in recombination was investigated by testing the ability of the MC-29 genome to donate sequences to its helper virus. The endogenous virus Rous-associated virus 0 (RAV-0) was used as a helper for MC-29, and its genome was compared by fingerprinting with that of the original RAV-0. In three separate isolates, the RAV-0 used as a helper for MC-29 had acquired new sequences near the 3' and 5' ends of its genome. The new 3' proximal sequences resembled the C region found in exogenous but not endogenous avian oncoviruses, and it probably imparted a higher growth rate to the recombinant compared with that imparted by RAV-0. One isolate also showed recombination within the *env* gene. Because the possibility that the recombination was with host cell information or with the original helper of MC-29 could not be excluded, it is concluded that the acquired sequences were derived from the MC-29 genome and, therefore, that this replication-defective virus is not defective in recombination. (24 refs)

- 79-5722 Intracellular State of Marek's Disease Virus DNA in Two Tumour-derived Chicken Cell Lines. (Eng) Kaschka-Dierich, C. (Institut für Klinische Virologie, Universität Erlangen-Nürnberg, Loschgestr. 7, 852 Erlangen, W. Germany); Nazerian, K.; Thomssen, R. *J Gen Virol* 44(2): 271-280; 1979.

The intracellular state of Marek's disease virus (MDV) DNA was investigated in two permanent chicken cell lines: HPRS-1, a virus nonproductive line established from an ovarian lymphoma of a chicken with MD; and MSB-1, a low virus producer line, established from a chicken with a MD splenic lymphoma. By repeated isopycnic centrifugation in cesium chloride, MDV DNA in the HPRS-1 line showed properties of integrated DNA, whereas both integrated and free virus DNA appeared to be present in the MSB-1 cells. Under denaturing conditions (0.1 M sodium hydroxide), the virus DNA remained associated with the cellular DNA as revealed by equilibrium centrifugation in CsCl and hybridization of the DNA in each single fraction with ³²P-labeled complementary RNA (³²P-cRNA) transcribed from the DNA of the GA strain of MDV. Shearing of HPRS-1 DNA to a mol wt of 8×10^6 released only part of the virus DNA with a density similar to that of free virus DNA, while a large proportion of MDV DNA still remained associated with the cellular DNA. Sedimentation velocity experiments with HPRS-1 and MSB-1 DNA originally fractionated on CsCl gradients revealed integrated virus DNA sequences in both cell lines and an additional peak of virus DNA at the position of free linear MDV DNA in the MSB-1 line. No MDV DNA sequences sedimenting at the expected position of covalently closed circular DNA of virus genome length (100-110S) was detected in any of these experiments. It is concluded that virus integration is a general phenomenon not restricted to malignant transformation. (31 refs)

- 79-5723 Macrophage Restriction of Marek's Disease Virus Replication and Lymphoma Cell Proliferation. (Eng) Lee, L. F. (United States Dept. Agriculture, Science and Education Admin., Federal Res. Regional Poultry Res. Lab., 3606 East Mount Hope Road, East Lansing, MI 48823). *J Immunol* 123(3): 1088-1091; 1979.

Macrophage function and its mechanism of action in the host immune response were studied. Treatment of spleen cells from White Leghorn chickens infected with the GA strain of Marek's disease virus (MDV) with anti-T serum and complement (C) had no effect on virus titer, but treatment with anti-B serum and C increased virus titer two- to threefold. Treatment with carbonyl iron/magnet to remove macrophages increased the virus titer 4- to 18-fold. The level of ¹²⁵I-iodo-2'-deoxyuridine uptake into MD-lymphoma cells was about the same for virus-inoculated and control line 6, chickens. In susceptible line 7, chickens, MDV inoculation induced a fivefold increase in isotope uptake; this increase was abolished when MDV spleen cells were pretreated with anti-Marek's disease tumor-associated surface antigen serum plus C. Pretreatment with carbonyl iron/magnet to remove macrophages resulted in a 70% increase in isotope uptake by normal spleen cells, a 200% increase by those from MDV-inoculated line 7, chickens, and a 300% increase in cells from similarly inoculated line 6, chickens. The results indicate that macrophages play a significant role in the restriction of MDV replication and the regulation of lymphoma cell proliferation in spleen cells from MDV-inoculated chickens. (18 refs)

- 79-5724 Expression of Genetic Resistance to an Oncogenic Herpesvirus at the Target Cell Level. (Eng) Gallatin, W. M. (Dept. Immunology, Univ. Alberta, Edmonton, Alberta, Canada); Longenecker, B. M. *Nature* 280(5723): 587-589; 1979.

The mechanism of non-major histocompatibility complex (non-MHC) resistance to oncogenic herpesviruses was studied in vitro and in vivo. Spleen cells from Marek's disease virus (MDV)-resistant line-6 chickens and from susceptible line-7 birds were incubated with herpesvirus of turkeys (HVT) for 1 hr, and infectious centers were assayed in ovo. Line-7 spleen cells induced 6.7 times more infectious centers than did line-6 spleen cells. In the in vivo tests, line-6 and line-7 spleen cells were transferred into separate groups of irradiated, histocompatible, third-party recipients, which were then exposed to MDV. More than four times more line-7 spleen cells than line-6 cells were infected with MDV. Injection of line-7 embryonic spleen cells into line-6 embryos did not significantly increase MD mortality. However, the transplantation of line-7 thymuses into newly hatched, thymectomized line-6 recipients rendered the line-6 birds much more susceptible to MD. These data suggest that genetic resistance to an oncogenic herpesvirus can be manifested at the target cell level and that the target cell for MDV-induced transformation is a T lymphocyte. While the mechanism of resistance at the target T lymphocyte level remains unknown, the viral adsorption studies suggest that resistant birds may have target cells with fewer virus receptors, receptors of lower affinity for virus, or fewer target cells with identical receptors. (20 refs)

- 79-5725 Xenogenization of Lymphocytes, Erythroblasts, and Tumor Cells. (Eng) Kobayashi, H. (Lab. Pathology, Cancer Inst., Hokkaido Univ. Sch. Medicine, Sapporo, Hokkaido, Japan); Takeichi, N.; Kuzumaki, N. *Hokkaido Univ Med Lib Ser* 10: 174 pp.; 1978.

The xenogenization (the immunologic regression of tumors induced by or artificially infected with membranous viruses in syngeneic and autochthonous hosts) of lymphocytes, erythroblasts, and tumor cells is reviewed in relation to immunologic tolerance, running syndrome, and hemolytic anemia. When newborn animals are injected with a nonlytic xenogenic virus, they become im-

munologically tolerant to the virus-specific antigens (VSA). If the virus is oncogenic, leukemia occasionally develops; and if the tolerant state is not complete or if there is a gradual decrease in the unresponsiveness to VSA, the runting syndrome is occasionally seen. Rats suffering from the runting syndrome often have an autoimmune hemolytic anemia. When adult immunologically competent animals are inoculated with xenogenized tumor cells, minimal tumor growth generally occurs and the tumor undergoes regression. If the immunogen is obtained from xenogenized tumor, there is an increased immune response when compared to nonvirus-infected tumor. In vitro studies indicate that xenogenized tumor cells have an increased level of specific reactivity when compared with nonxenogenized tumor cells. The applicability of these findings to human disease is only speculative at present. (345 refs)

- 79-5726 Rescue of a Thymotropic, Leukemogenic C-Type Virus from Cultured, Nonproducer Lymphoma Cells of Strain C57BL/Ka Mice. (Eng) Lieberman, M. (Cancer Biology Res. Lab., Dept. Radiology, Stanford Univ. Sch. Medicine, Stanford, CA 94305); Decleve, A.; Ihle, J. N.; Kaplan, H. S. *Virology* 97(1): 12-21; 1979.

The rescue of a thymotropic, leukemogenic C-type virus from a nonproducer cell line by infection with a B-ecotropic, non-thymotropic, nonleukemogenic C57BL/Ka retrovirus, BL/Ka(B), is reported. A permanent cell line, BL/RL₁₂-NP, derived from a radiation-induced C57BL/Ka mouse lymphoid tumor, has remained devoid of murine leukemia virus expression, except for the rare, sporadic initiation of virus production in some cultures. It can, however, be stably infected by radiation leukemia virus (RadLV), and the progeny virus population retains the biological and serological properties of the parental RadLV. The cells can also be infected by the C57BL/Ka virus isolate BL/Ka(B). In the latter situation, the emerging virus particles may exhibit thymotropic and leukemogenic (T+L+) attributes similar to those of RadLV while retaining at least some of the envelope determinants of BL/Ka(B). These observations suggest that, following productive infection by a nonleukemogenic helper virus, oncogenic sequences endogenous to the nonproducer lymphoma cells may be packaged in infectious progeny virions. The data are interpreted as providing strong support for the existence, in radiogenic lymphomas, of defective T+L+ sequences, designated RadLV-O. Possible mechanisms by which RadLV-O is later expressed as an infectious leukemogenic virus are presented. (27 refs)

- 79-5727 Induction of B-tropic and N-tropic Murine Leukemia Virus from B10.BR/SgLi Mouse Embryo Cell Lines by 5-Iodo-2'-deoxyuridine. (Eng) Moll, B. (Dept. Pathology, Lenox Hill Hosp., New York, NY 10021); Hartley, J. W.; Rowe, W. P. *J Natl Cancer Inst* 63(1): 213-217; 1979.

Although there is an excellent correlation between the efficiency with which N-tropic ecotropic murine leukemia virus (MuLV) can be induced by 5-iodo-2'-deoxyuridine (IUdR) or 5-bromodeoxyuridine (BUdR) from mouse embryo cultures and the frequency with which the virus is detectable in adults of the same strains, the correlation between natural occurrence and induction efficiency is not true for B-tropic virus. This study shows that a subline of the B10.BR mouse strain has a high level of B-tropic virus and that embryo cultures from the subline contain IUdR-inducible B- and N-tropic ecotropic MuLV. In contrast to the original B10.BR/SgSn congenic mouse strain, adults of the B10.BR/SgLi subline showed a high level of expression of B-tropic

ecotropic MuLV (94% were virus-positive in one test). Both B- and N-tropic ecotropic MuLV were induced by IUdR in cultures of two virus-free cell lines derived from embryos of B10.BR/SgLi mice, as measured by XC-cell plaque assay of the cell culture medium and subsequent assay of the harvested virus on BALB/c and NIH Swiss embryo cultures. The IUdR-induced virus isolates were similar to prototypic B- and N-tropic ecotropic MuLV in their XC positivity, neutralization pattern, efficient infection of SC-1 and permissive Fv-1-type mouse cells, partial restriction by Fv-1-mb mouse cells, and failure to infect mink lung cells. Of eight additional B10.BR/SgLi cell lines tested, 2 produced B-tropic virus spontaneously, 3 were inducible for both B- and N-tropic viruses, and 3 were inducible for only N-tropic virus. Confirmation that the B-tropic virus of the B10.BR/SgLi cell line is carried as a genetic element was obtained in two ways. First, four clonal lines of an inducible cell line were derived from single cells and four yielded B- and N-tropic virus after IUdR treatment. Second, most of the cultures of F₁ embryos derived from matings of B10.BR/SgLi males with NFS/N or A/J females were inducible for both B- and N-tropic viruses, whereas no ecotropic virus was induced from the NFS/N strain, and only rarely was N-tropic virus induced from the A/J strain. Thus, the information for B-tropic MuLV as well as that for N-tropic MuLV was transmitted as a genetic element in the B10.BR/SgLi subline. (28 refs)

- 79-5728 Biological Characterization of a Leukemogenic Virus Isolated from the CFW Mouse. (Eng) Ball, J. K. (Cancer Res. Lab., Univ. Western Ontario, London, Ontario N6A 5B7, Canada); McCarter, J. A. *Cancer Res* 39(8): 3080-3088; 1979.

Extracts of thymic lymphomas induced in CFW/D mice by dimethylbenz(a)anthracene (DMBA) are leukemogenic when injected into intrarenal thymic grafts. Tumor cell lines established in vitro from tumors induced by these extracts release a C-type virus. This tissue culture (TC)-derived virus (TC-DMBALV: virus produced by TC cell lines established from tumors induced by cell-free tumor extracts or TC cell supernatants) is highly leukemogenic (minimum infectious titer of 1.6×10^6 IU/ml) when injected into 24-hr-old thymus grafts placed under the kidney capsules of normal 6-wk-old adults. The latent period (time in days to tumor detection in 50% of the injected grafts using undiluted TC virus preparations) is very short (30 days postinjection). Thymic lymphomas induced by virus isolated from DMBA-induced tumor virus cells and by TC-DMBALV have been characterized as T-cell thymomas. Productive infection with either of the viral isolates could not be initiated on any of a wide variety of TC cell lines under conditions that readily permitted the recovery of xenotropic and ecotropic C-type viruses in control experiments. The data indicate that, unlike radiation leukemia virus, (1) TC-DMBALV does not infect cell lines in culture and (2) virus isolated from DMBA-induced tumor virus cells does not appear to be accompanied by detectable and/or recoverable levels of xenotropic or ecotropic C-type viruses. TC-DMBALV has a buoyant density and RNA genome characteristic of C-type particles. Polyacrylamide-sodium dodecyl sulfate gel analysis of the viral proteins indicated a markedly altered pattern of gag-coded proteins compared with those of the xenotropic virus induced from a lymphoid-derived cell line established from CFW/D mice. - 79-5729 A Murine Sarcoma Virus-associated Protein Kinase: Interaction with Actin and Microtubular Protein.

(Eng) Sen, A. (Lab. Viral Carcinogenesis, NCI, Bethesda, MD 20205); Todaro, G. J. *Cell* 17(2): 347-356; 1979.

A low mol-wt (approx 15K) protein phosphokinase enzyme that binds to actin was isolated from the m3 variant of murine sarcoma virus produced, with a helper murine leukemia virus, by 3B11C mouse 3T3 cells. The kinase activity was not detected in the helper virus preparations. It was purified by Sephadex G-75 gel filtration and affinity chromatography on actin-Sepharose conjugates. In assays using phospho-vin as an exogenous substrate, the enzyme was released from the virions at Triton X-100 concentrations >0.12%. The kinase was inhibited by Triton at concentrations >0.01%, which indicates that it is an internal protein packaged in the virion particles. Only 10%-15% of a high mol-wt (approx 40K) kinase bound to the actin-Sepharose conjugate, but almost 90% of the low mol-wt enzyme was recovered from the actin-bound kinase preparation. The binding of actin molecules to the enzyme was accompanied by inhibition of phosphorylation reactions catalyzed by the enzyme in the presence of actin. The actin-binding enzyme showed a lower but detectable binding to microtubular proteins, and it inhibited the in vitro polymerization of tubulin. This study represents the first isolation of a sarcoma virus-associated protein with the ability to interact directly with two major components of the cytoskeletal system. (42 refs)

79-5730 Composition, Arrangement and Cleavage of the Mouse Mammary Tumor Virus Polyprotein Precursor Pr77^{gag} and p110^{gag}. (Eng) Dickson, C. (Imperial Cancer Res. Fund Lab., P.O. Box 123, Lincoln's Inn Fields, London WC2A 3PX, England); Atterwill, M. *Cell* 17(4): 1003-1012; 1979.

The [¹⁴C]lysine- and [¹⁴C]arginine-labeled tryptic peptide maps of the nonglycosylated structural proteins of murine mammary tumor virus, the putative *gag* gene-related precursors Pr77^{gag} and p110^{gag}, and the cleavage intermediates derived from Pr77^{gag} were determined. The proteins were labeled with [¹⁴C]lysine and [¹⁴C]arginine so that all but one of the tryptic peptides released from a protein could be detected. As judged from the peptide maps, Pr77^{gag} contained the complete sequences of the four major internal proteins of the virion (p27, pp21, p14 and p10) and possibly a fifth highly basic protein (p8) also found in the virion. The putative cleavage intermediates lacked some tryptic peptides that could be assigned to one or more of the major virion proteins and thus allow a scheme for the cleavage events to be constructed. p110^{gag} contained all tryptic peptides found in Pr77^{gag}, plus some additional peptides. A minor virion protein p30 included the peptides of p14 as well as some of the additional peptides present in p110^{gag} suggesting a precursor-product relationship between the p110^{gag} and p30. The data support the authors' proposal that there are three protein precursors that include, at least in part, the *gag* gene region of the virion -- p160 (potentially a *gag/pol* precursor), p110^{gag} and Pr77^{gag} -- and that the arrangement of the virion proteins within the *gag* gene (pr77 *gag*) is p10-pp21-p27-p14. 79-5731 Mouse Mammary Tumor Cell Surface Antigens. II. Immunogenicity and Expression of MMTV Proteins in the Mouse. (Eng) Fine, D. (Viral Oncology Program, Frederick Cancer Res. Center, Frederick, MD 21701); Arthur, L.; Massey, R.; Schochetman, G. In: *Biological Markers of Neoplasia: Basic and Applied Aspects*. Proceedings of an international conference held 22-26 May 1978, Leesburg, VA. Ruddon, R. W., ed. (New York; Elsevier): 590 pp.; 143-168; 1978.

Sera and tissues of mice with different incidences of spontaneous mammary tumors were examined for mouse mammary tumor virus (MMTV) gp52, and the humoral and cellular immunity that occurs against both the virus and the tumor cells was characterized. A specific radioimmunoassay for MMTV gp52 showed that mammary tumor and normal mammary gland tissues from high tumor strains contained 1,500 and 600 nanograms of gp52/mg tissue, respectively. Lymph nodes draining the mammary gland and normal tissues with secretory functions (salivary glands, seminal vesicles, and coagulating glands) also contained gp52. Male and female mice of strains expressing MMTV gp52 and having moderate to high incidences of mammary tumors had antibodies that specifically precipitated MMTV, whereas no antibody was detected in strains with low mammary tumor incidences. Reactivity of natural sera for MMTV showed competition with purified MMTV gp52. High-titered precipitating sera from BALB/c NIV and feral mice specifically precipitated purified MMTV gp52. Gp36 was also immunogenic, because strains of mice with low to moderate tumor incidences developed precipitating antibodies to gp36 and gp52 when inoculated with purified MMTV. Natural sera as well as sera from MMTV-inoculated mice with MMTV precipitating antibody were also cytotoxic for mammary tumor cells in a complement-dependent assay. These sera were specific for cells expressing MMTV antigens, and the development of both precipitating and cytotoxic antibodies was age-dependent. An age-dependent blastogenic response that recognized MMTV and murine leukemia virus and the purified major glycoproteins of the two viruses was found in these same strains of mice. Thus, the development of both humoral and cell-mediated immune responses in the C3Hf mouse demonstrates the ability of the host to recognize endogenous MMTV. (20 refs)

79-5732 Acceleration of Mammary Cancer Development by Grafting of Fetal Mammary Mesenchymes in C3H Mice. (Eng) Sakakura, T. (Lab. Experimental Pathology, Aichi Cancer Center Res. Inst., Kanokoden, Tashiro-cho, Chikusa-ku, Nagoya 464, Japan); Sakagami, Y.; Nishizuka, Y. *Gann* 70(4): 459-466; 1979.

Mammary epithelial hyperplasia was induced in 9-wk-old, syngeneic, female C3H/HeN mice, which are carriers of milk-transmitted virulent virus (MTV-S), and in C3H/fHeN mice, which do not carry the virus. Transplantation of fetal mammary gland mesenchyme into the mammary glands of both strains resulted in focal reenactment of events that normally occur during fetal and early postnatal development of the mammary gland. The portions of the recipient's mammary duct system in contact with the fetal mammary mesenchyme underwent branching and proliferation in a pattern resembling that of rudimentary mammary gland development. In mice carrying MTV-S, mammary cancers of Types A and B appeared earlier and more frequently in the mammary glands that had received transplants of fetal mammary mesenchyme, compared with those in the glands that received no fetal mesenchyme. Some of the smaller cancers were shown to develop directly from portions of the mammary gland interacting with fetal mammary mesenchyme, without prior formation of typical hyperplastic alveolar nodules. Cancers did not appear in similarly treated mammary glands of C3H mice not carrying MTV-S. The results suggest that nonhormonal, and probably non-viral factors that stimulate focal proliferation in the mammary duct system as a result of fetal mesenchyme transplantation accelerate local development of mammary cancers. (15 refs)

79-5733 Diversity of Mammary Tumor Viral Genes Within the Genus *Mus*, the species *Mus musculus*, and the strain

C3H. (Eng) Drohan, W. (Lab. Viral Carcinogenesis, NCI, Bethesda, MD 20205); Schlom, J. *J Virol* 31(1): 53-62; 1979.

Proviral sequences related, or identical, to tumor-associated (TA)-sequence RNA are found in the DNA's of spontaneous mammary tumors that arise early in the life of several high-tumor-incidence mouse strains. These sequences are absent in the DNA's of mammary tumors that occur later in the life of low- and moderate-incidence strains, as well as in apparently normal tissues of a variety of inbred mouse strains, feral mice, and other species and subspecies of *Mus*. Sequences represented in TA sequence RNA, however, are present as endogenous provirus in GR mice (at approx 4 copies per haploid genome) and in 2/5 substrains of C3H mice tested (at approx 1 copy per haploid genome). The two substrains of C3H mice positive for endogenous TA sequence provirus were recently (around 1930) separated from the negative substrains of C3H mice. The results may be explained by the unlikely chance segregation of proviral sequences or by the recent integration of viral genes (within the last few decades). Whereas radioactively labeled mouse mammary tumor virus 60S-70S RNA or complementary DNA detected mouse mammary tumor virus-related proviral information in all laboratory mouse strains, feral mice, subspecies of *M. musculus*, and other species of *Mus*, the use of TA sequence RNA clearly revealed the genetic diversity that may exist between different colonies or substrains of "inbred" laboratory mice commonly used in cancer research. (38 refs)

79-5734 Induction of Mouse Mammary Tumor Virus RNA in Mammary Tumors of BALB/c Mice Treated with Urethane, X-Irradiation, and Hormones. (Eng) Michalides, R. (Div. Virology, Antoni van Leeuwenhoekhuis, Netherlands Cancer Inst., 1066 CX Amsterdam, Netherlands); van Deemter, L.; Nusse, R.; Hageman, P. *J Virol* 31(1): 63-72; 1979.

The involvement of mouse mammary tumor virus (MTV) in the development of mammary tumors of nonviral etiology in BALB/c mice was studied by measuring the levels of MTV RNA, MTV DNA, and MTV proteins in spontaneously arising and hormonally, chemically, and/or physically induced mammary tumors of BALB/c females. Spontaneous mammary tumors contained very low levels of MTV RNA; $4 \times 10^{-6}\%$ of the cytoplasmic RNA was MTV RNA. No MTV proteins could be demonstrated by using sensitive radioimmunoassays for MTV proteins p27 and gp52. Mammary tumors induced by treatments with urethane or x-rays alone contained higher levels of MTV RNA; these tumors contained 3- and 19-fold more MTV RNA, respectively, compared with spontaneous mammary tumors. Mammary tumors induced by combined treatment with urethane and x-rays expressed high levels of MTV RNA in the mammary tumors; a 1,724-fold increase in MTV RNA content compared with spontaneous mammary tumors was observed. However, very low levels of MTV proteins gp52 and p27 were detected, suggesting some kind of impairment at translation of the MTV RNA. MTV RNA was also induced by this treatment in mammary glands and spleens, but not in the livers of tumor-bearing animals. BALB/c females continuously exposed to prolactin contained high levels of MTV RNA and MTV proteins in stimulated mammary glands and in the hormonally induced mammary tumors. These findings suggest that MTV is not responsible for the maintenance and probably also not for the development of all murine mammary cancers. (30 refs)

and Murine Leukemia Virus (MuLV) Surface-associated Antigens. (Eng) Schochetman, G. (Viral Oncology Program, Frederick Cancer Res. Center, Frederick, MD 21701); Arthur, L. O.; Fine, D. L.; Massey, R. In: *Biological Markers of Neoplasia: Basic and Applied Aspects*. Proceedings of an international conference held 22-26 May 1978, Leesburg, VA. Ruddon, R. W., ed. (New York; Elsevier): 590 pp.; 115-141; 1978.

The intracellular regulation and synthesis of mouse mammary tumor virus (MMTV) components were studied, and virus-specific cell-surface antigens (CSA) were identified as potential targets for immune surveillance by the mouse. Labeled viral antigens were analyzed by immunoprecipitation with monospecific antisera directed against MMTV and murine leukemia virus (MuLV) proteins followed by gel electrophoresis. On cultured virus- and non-virus-producing cells, both MMTV gp52 and MuLV gp70 were iodinated, even though the gp52 precursor polyprotein (gPr75 - MMTV env) was readily isolated from the cells. In addition, gp52 and gp70 were iodinated on primary mammary tumor cells never placed in culture, whereas only gp70 was iodinated on lymphocytes from the same tumor-bearing animal. Cultured tumor cells that simultaneously produced MMTV and MuLV also contained a possible precursor to gp70 and two CSA of 85,000 and 95,000 daltons that were analogous to the Gross CSA (GCSA). Extracellular MMTV and MuLV from these cells contained only labeled gp52 and gp70, respectively, indicating that these two viral envelope glycoproteins are present on mutually exclusive viral budding sites that are distinct from the surface sites occupied by GCSA. The galactose oxidase labeling method also demonstrated the cell-surface locations of gp52, gp70, and the possible gp70 precursor. However, this method also labeled MMTV gp36, indicating that at least its carbohydrate regions are exposed. These results demonstrate that gPr75 is cleaved prior to the appearance of gp52 on the cell surface and that gp52, gp70, and, possibly, gp36 are tumor CSA and potential targets for the immune response in mice. (25 refs)

79-5736 Effect of Parity Regimen on the Rate of Occurrence of Mammary Tumors in A, C3H, and RIII Mice. (Eng) Moore, D. H. (Dept. Microbiology and Immunology, Hahnemann Medical Coll. and Hosp., Philadelphia, PA 19102); Holben, J. A. *Int J Cancer* 24(2): 161-164; 1979.

The effect of breeding regimen (early in life, late, continuous, or not at all) on the incidence of mammary tumors was studied in A, RIII, and C3H mice. The response to the breeding regimen was different in each of the three strains. The C3H stock was affected least, although the tumor occurrence rate was slower in virgins. In both A and RIII, only one litter at puberty resulted in the tumors occurring over the greatest age range; in RIII mice, the occurrence rate and the mean tumor age were similar to those of virgins. Normal continuous breeding caused the earliest tumors in all three strains, although in RIII mice, breeding after 18 wk of age also caused very early tumors. The response of the RIII strain to parity variations was more like that of humans than was the response of either of the other strains. Removal of the milk-transmitted virus from these strains by foster-nursing resulted in vastly different mammary tumor occurrence rates, the quantitative changes being different in each mouse strain. 79-5735 Mouse Mammary Tumor Cell Surface Antigens (CSA). I. Mouse Mammary Tumor Virus (MMTV)

79-5737 Virus Production by Abelson Murine Leukemia Virus-transformed Lymphoid Cells. (Eng) Shields, A. (Dept. Biology, Massachusetts Inst. Technology, Cambridge, MA

02139); Rosenberg, N.; Baltimore, D. *J Virol* 31(2): 557-567; 1979.

A systematic investigation was made of virus production by Abelson murine leukemia virus (A-MuLV)-transformed cells. Lymphoid cell lines obtained by in vitro transformation of NIH/Swiss bone marrow cells with A-MuLV can be divided into three classes: producers releasing reverse transcriptase (RT)-containing particles and infectious virus; nonproducers releasing no viral particles; and defective producers, the most common phenotype, releasing particulate RT in the absence of infectious virus. When these cell lines were analyzed 1-2 wk after their isolation, however, all produced infectious virus. Because these cell lines were carried in culture, many ceased to release infectious virus but produced defective virions. One defective producer, SWR4, was studied extensively. The particles it produces have the same density as that of virions of Moloney murine leukemia virus (M-MuLV). The particles contain no 35S-70S RNA, as determined by analysis of [³H]uridine-labeled particles, and they exhibit no endogenous RT activity. Although the RT enzyme is of normal size, the major structural protein of the defective virions has a mol wt of 28,000 (p28), in contrast to the p30 of M-MuLV, and no viral glycoprotein is evident. The defective particles do not appear to arise either from the helper virus or from Abelson virus. An alteration of the protein of the helper virus is an unlikely source of p28, because particles produced by lymphoid cells transformed with another strain of M-MuLV as helper (M-MuLV-TB) contained p28 with an unaltered cleavage pattern, although M-MuLV-TB p30 differs from M-MuLV p30. The A-MuLV genome lacks the capacity to code for the RT and p28 of the defective virions and, therefore, cannot be the source of the defective virions. Clones of fibroblasts infected with A-MuLV only occasionally produce defective particles. The defective particles therefore probably arose from an endogenous virus that is preferentially expressed in the class of lymphoid cells transformed by A-MuLV. This interpretation implies that most of A-MuLV-transformed lymphoid cells completely lose expression of the helper virus genome. (35 refs)

79-5738 Phenotypic Mixing Between Murine Oncoviruses and Murine Cytomegalovirus. (Eng) Schnitzer, T. J. (Imperial Cancer Res. Fund, Lincoln's Inn Fields, London WC2A 3PX, England); Gonczol, E. *J Gen Virol* 43(3): 691-695; 1979.

In vitro interactions between murine cytomegalovirus (MCMV) and murine leukemia viruses (MuLV's), two groups of enveloped viruses capable of causing persistent or latent infections in vivo, were examined for evidence of phenotypic mixing, since pseudotype formation could alter the spread of these viruses and be important in their pathogenesis. The growth of MCMV in murine cells productively infected with ecotropic MuLV resulted in the production of phenotypically mixed particles having the envelope antigens of MuLV and the genome of MCMV [MCMV(MuLV) pseudotypes]. The identity of these pseudotype particles was confirmed by the use of specific anti-MuLV serum and by the demonstration of restriction, due to viral interference, of the penetration of these particles on MuLV-infected murine cells. This restriction was independent of N- or B-tropism. The production of reverse pseudotypes could not be examined because of the lytic effects of MCMV on the requisite assay cells. (28 refs)

79-5739 Identification of Proteins Specific to Friend Strain of Spleen Focus Forming Virus (SFFV). (Eng) Ikawa, Y.

(Dept. Viral Oncology, Cancer Inst., Tokyo, Japan); Yoshida, M.; Yoshikura, H. *Proc Japan Acad, Ser B: Phys Biol Sci* 54(10): 651-656; 1978.

The identification of 55,000- and 120,000-dalton proteins as spleen focus-forming virus (SFFV)-specific proteins is described. The former cross-reacted with anti-Rauscher murine leukemia virus gp70 serum and was abundant in SFFV-producing and nonproducing SFFV-infected erythroleukemia clones. A large quantity of the other protein was detected in SFFV-infected normal rat kidney cells. These proteins are probably coded for by the SFFV genome. (20 refs)

79-5740 Spleen Focus-forming Friend Virus: Identification of Genomic RNA and Its Relationship to Helper Virus RNA. (Eng) Evans, L. H. (Dept. Molecular Biology, Univ. California, Berkeley, CA 94720); Duesberg, P. H.; Troxler, D. H.; Scolnick, E. M. *J Virol* 31(1): 133-146; 1979.

The genome of the defective, murine spleen focus-forming Friend virus (SFFV) was identified as a 50S RNA complex consisting of 32S RNA monomers. Electrophoretic mobility and the mol wt of unique RNase T₁-resistant oligonucleotides (T₁-oligonucleotides) indicated that the 32S RNA had a complexity of about 7.4 kilobases. Hybridization with DNA complementary to Friend murine leukemia virus (Fr-MLV) distinguished two sets of nucleotide sequences in 32S SFFV RNA, 74% which were Fr-MLV related and 26% which were SFFV specific. By the same method, SFFV RNA was 48% related to Moloney MLV. A total of 23 large T₁-oligonucleotides of SFFV and 43 of Fr-MLV RNA's, were resolved. The former were classified as follows on the basis of the relationship between the SFFV and Fr-MLV RNA's: (1) seven which had homologous equivalents in Fr-MLV RNA; (2) six more which could be isolated from SFFV RNA-Fr-MLV complementary DNA hybrids treated with RNases A and T₁; (3) eight more which were isolated from hybrids treated with RNases T₁; and (4) two which did not have Fr-MLV-related counterparts. Surprisingly, the two class 4 oligonucleotides had homologous counterparts in the RNA of six amphotropic MLVs including mink cell focus-forming and HIX-MLVs analyzed previously. The map locations of the 23 SFFV T₁-oligonucleotides relative to the 3' polyadenylic acid coordinate of SFFV RNA were deduced from the size of the smallest polyadenylic acid-tagged RNA fragment from which a given oligonucleotide was isolated. The resulting oligonucleotide map could be divided roughly into three segments: two terminal segments which are mosaics of oligonucleotides of classes 1, 2, and 3, and an internal segment between 2 and 2.5 kilobases from the 3' end containing the two oligonucleotides shared with amphotropic MLVs. Since SFFV RNA consists predominantly of sequence elements related to ecotropic and amphotropic helper-independent MLVs, it would appear that the transforming gene of SFFV is not a major specific sequence unrelated to genes of helper viruses, as is the case with Rous sarcoma and probably with other defective sarcoma and acute leukemia viruses. (53 refs)

79-5741 Pluripotential Stem Cell Replication in Continuous Human, Prosimian, and Murine Bone Marrow Culture. (Eng) Moore, M. A. (Labs. Developmental Hematopoiesis, Sloan Kettering Inst. Cancer Res., 1250 First Ave., New York, NY 10021); Sheridan, A. P. *Blood Cells* 5(2): 297-311; 1979.

The capacity of Friend leukemia virus to transform pluripotential

stem cells (CFU-s) or committed progenitor cells in continuous marrow cultures was studied using a cloned stock of Friend helper C-type virus (F-MuLV) or spleen focus-forming virus (SFFV) isolated free of replicating helper virus in nonproducer fibroblast lines. Marrow cultures infected with F-MuLV in the absence of SFFV began to deviate from normal by 10-11 wk. The deviation was marked by a stabilization and then increase in cell production with an increasing predominance of immature granulocytic elements and granulocyte-macrophage progenitors (CFU-c). At 15 wk, a marked increase in the cloning efficiency of the F-MuLV-infected cultures was associated with the predominance of small, tight, cerebrospinal fluid (CSF)-dependent colonies composed of maturing granulocytes. Cultures infected with SFFV plus F-MuLV did not exhibit the phenotypic changes seen in the F-MuLV-infected cultures. Significant changes in hematopoiesis were seen within 3 wk of infection of the cells with the Kirsten murine sarcoma virus pseudotype. These involved conversion to a predominantly macrophage morphology with drastic declines in CFU-c and CFU-s. In human bone marrow cultures, there was a sustained replication of CFU-c and production of myeloid cells for several weeks; colony size, morphology, and CSF responsiveness were indistinguishable from those of normal cultures. The *Tupaia*, one of the most primitive living prosimians, is hematologically very similar to humans, but an adherent marrow environment established from this species was similar to that seen in the mouse. (16 refs)

- 79-5742 Group-specific Cytolytic Antibody Directed Against the Major Glycoprotein (gp70) of Murine Leukemia Viruses in Serum of Mice with Dormant FLV Infections. (Eng) Callahan, R. M. (Dept. Microbiology, Thomas Jefferson Univ., Philadelphia, PA 19107); Marx, P. A.; Wheelock, E. F. *Virology* 97(1): 55-67; 1979.

The antibody in Friend leukemia virus (FLV) immune serum (FVIS) that is responsible for the lysis of Friend erythroleukemia (FLC-745) cells was studied. Gp70 was the only FLV antigen on the FLC-745 cells that was able to be a target for cytolysis by virus-specific antibody, and a nonvirion FLV cellular antigen was excluded as a target for FVIS cytolytic activity. Determination of the group specificity of the cytolytic activity of serum from mice with dormant FLV infections indicated that a group-specific gp70 antibody in FVIS was responsible for FLC-745 cell lysis and distinguished FVIS from Friend/Moloney/Rauscher murine leukemia virus-specific cytolytic antibody. Competition radioimmunoassay with FLV, AKR, and feline leukemia viruses indicated that FVIS must contain type-specific gp70 antibody in addition to a group-specific cytolytic antibody. However, this type-specific antibody was not cytolytic for FLC-745 cells, since AKR virus was able to block cytolysis completely. The data suggest that the cytolytic antibody in FVIS is directed against gp70, and they suggest that this antibody is involved in the suppression of FLV to a dormant state. (37 refs)

- 79-5743 Anti-Friend Virus Antibody Is Associated with Recovery from Viremia and Loss of Viral Leukemia Cell-Surface Antigens in Leukemic Mice. Identification of Rfv-3 as a Gene Locus Influencing Antibody Production. (Eng) Doig, D. (Rocky Mountain Lab., Natl. Inst. Allergy and Infectious Diseases, NIH, Hamilton MT)(59840); Chesebro, B. *J Exp Med* 150(1): 10-19; 1979.

The mechanism of action of the non-H-2 gene Rfv-3 was studied in

several mouse strains. Rfv-3 influenced Friend virus (FV) viremia, loss of FV-induced cell-surface antigens from leukemia cells, and generation of anti-FV antibodies. At 30-90 days after FV infection, leukemic spleen cells from (B10.A x A)F₁ and (B10.A x A.BY)F₁ mice (Rfv-3 r/s) had low FV-induced cell-surface antigen expression compared with leukemic spleen cells from A and A.BY mice (Rfv-3^{+/+}). In addition, these F₁ mice recovered from viremia and generated cytotoxic anti-FV antibodies. A and A.BY mice did not recover from viremia and they failed to generate anti-FV antibodies. Anti-FV leukemia cell antibody appeared to mediate FV-antigen loss, because a decrease of FV cell-surface antigens occurred at the same time as anti-FV antibody appeared in the plasma of F₁ mice, and passive transfer of anti-FV antisera induced modulation of FV cell-surface antigens. Rfv-3 did not influence an intrinsic ability of FV antigens to be modulated from Rfv-3^{+/+} leukemia cells, because FV antigen loss from Rfv-3^{+/+} spleen cells occurred after the cells were transferred to an immune environment. (28 refs)

- 79-5744 The Generation and Specificity of Cytotoxic T Cells Raised Against Syngeneic Tumor Cells Bearing AKR/Gross Murine Leukemia Virus Antigens. (Eng) Green, W. R. (Basic Immunology Program, Fred Hutchinson Cancer Res. Center, Seattle, WA 98104); Nowinski, R. C.; Henney, C. S. *J Exp Med* 150(1): 51-66; 1979.

Experiments aimed at determining whether the ability to generate cytotoxic activity against syngeneic gross cell-surface antigen-positive tumors correlates with Rgv-directed resistance to leukemogenesis were performed. Rgv is a locus mapping in the region that controls immune responsiveness. Efforts were made to generate C57BL/6 cytotoxic effector cells to a syngeneic leukemia (E male G2) bearing AKR/Gross virus antigens (GVA). No significant cytotoxicity was induced by immunization with up to 10⁸ irradiated E male G2 cells, even when cells from such primed animals were subsequently restimulated with E male G2 cells in vitro. Consequently, C57BL/6 mice were immunized with an allogeneic, virus-producing AKR leukemia cell line (AKR SL3). Peritoneal exudate cells and, to a lesser degree, spleen cells from these mice showed significant lytic activity toward the immunizing allogeneic tumor but not toward E male G2. When spleen cells were harvested from animals approx 10 days after injection of AKR SL3 and rechallenged in vitro with either E male G2 or AKR.H-2b SL1, another tumor that displays AKR/GVA, a vigorous cytotoxic response against E male G2 and AKR.H-2b was obtained. Effector cells generated by AKR SL3 priming followed by in vitro stimulation with E male G2 or AKR H.2b SL1 lysed only cells of the H-2b haplotype that were strongly positive for the display of serologically detectable AKR/GVA. Thus, AKR SL3 cells were not lysed nor were EL4 cells (H-2b, but only weakly positive for gp70). Cells not bearing the murine leukemia virus antigens tested for, such as P815 mastocytoma cells and spleen cell "blasts" from C57BL/6 and CBA (H-2k) mice, were also not susceptible to attack. The cytotoxic effector cells induced bore Thy 1.2 alloantigen and were of the Lyt 1 + 2 + phenotype. Collectively, these findings are consistent with the conclusion that the cytotoxic T cells raised against E male G2 are directed against GVA and are H-2-restricted. (33 refs)

- 79-5745 Loss of Proviral DNA Sequences in a Revertant of Kirsten Sarcoma Virus-transformed Murine Fibroblasts. (Eng) Trainor, C. D. (Lab. Tumor Cell Biology, NCI, NIH, Bethesda, MD 20014); Reitz, M. S. *J Gen Virol* 44(1): 245-249; 1979.

The revertant cell line (K-BALB SR¹²¹²), derived as a single cell clone from a clonal line of murine fibroblasts (K-BALB) transformed by nonproductive infection with Kirsten murine sarcoma virus (Ki-MSV), has normal morphology and growth kinetics and, unlike the transformed parent cell line, lacks a rescuable sarcoma virus. This reversion was found to correlate with low to undetectable levels of expression of cellular Ki-MSV-specific RNA and a reduction of proviral sequences in the cell DNA to a level equivalent to that found in the uninfected BALB cells with a normal phenotype. The data indicate that phenotypic reversion has occurred as a consequence of the loss of part or all of the sarcoma provirus, either by chromosome rearrangement or provirus excision. (19 refs)

- 79-5746 Cycloheximide-dependent Reversion of Human Cells Transformed by MSV and Chemical Carcinogen. (Eng) Cho, H. Y. (Dept. Experimental Pathology, Walter Reed Army Inst. Res., Washington, DC 20012); Rhim, J. S. *Science* 205(4407): 691-693; 1979.

Evidence is presented that morphologic reversion and selective inhibition of growth can be observed in virally or chemically transformed human cells after treatment with protein synthesis inhibitor cycloheximide (CH). CH, at a concentration of 0.08 $\mu\text{g}/\text{ml}$, induced a flat morphology within 24-48 hr and a low saturation density in human osteosarcoma cells transformed by Kirsten murine sarcoma virus or N-methyl-N'-nitro-N-nitrosoguanidine. Removal of CH caused both transformed cells to revert to the transformed phenotype. The demonstration of cell-surface antigens, cross-reacted with antisera induced by extracts of both types of transformed human cells, was dependent on the presence or absence of CH in the culture medium. The results show that protein synthesis is required to maintain the transformed state in virally or chemically transformed human cells. (20 refs)

- 79-5747 Effects of Protease Inhibitors on Chemical Induction of Type C Virus. (Eng) Long, C. W. (Frederick Cancer Res. Center, P.O. Box B, Building 560, Frederick, MD 21701); Bruszewski, J. A.; Christensen, W. L.; Suk, W. A. *Cancer Res* 39(8): 2995-2999; 1979.

The effects of protease inhibitors on the chemical induction of endogenous xenotropic C-type virus from Kirsten sarcoma virus-transformed BALB/c 3T3 mouse cells was examined. Two distinct classes of protease inhibitors, the trypsin inhibitor α -N-tosyl-L-lysine chloromethyl ketone and two naturally occurring oligopeptide inhibitors, antipain and leupeptin, were found to inhibit induction of virus by cycloheximide and histidinol. Virus activation by 5-iododeoxyuridine was inhibited to a lesser degree. During the time cells were exposed to these compounds, there was little inhibition of [³H]uridine incorporation into total cellular RNA or polyadenylic acid-containing cytoplasmic messenger RNA, suggesting that inhibition of proteolysis, and not RNA transcription, was responsible for blocking virus induction. (41 refs)

- 79-5748 Decrease in Epidermal Growth Factor Receptor Levels and Production of Material Enhancing Epidermal Growth Factor Binding Accompany the Temperature-dependent Changes from Normal to Transformed Phenotype. (Eng) Guinivan, P. (Div. Genetics, Dept. Pediatrics, Coll.

Medicine, Pennsylvania State Univ., Hershey, PA 17033); Ladda, R. L. *Proc Natl Acad Sci USA* 76(7): 3377-3381; 1979.

The growth-promoting activity and binding characteristics of epidermal growth factor (EGF) on normal rat kidney (NRK) cells and derivatives of these cells transformed by Kirsten murine sarcoma virus (KNRK cells) and a temperature-sensitive mutant of the virus (Ts cells) were investigated. The Ts cells exhibited a normal monolayer morphology identical to that observed for uninfected NRK cells at the nonpermissive temperature (39 C), but they grew as multilayered foci resembling KNRK cells at the permissive temperature (32 C). NRK cell division was stimulated by EGF, and these cells showed high levels of EGF receptors, as determined by ¹²⁵I-labeled EGF binding. KNRK cells were unresponsive to EGF, and no EGF receptors were detectable. Ts cells also were unresponsive to EGF at both temperatures, but they exhibited just-detectable EGF binding at 32 C and 10%-15% of NRK cell binding at 39 C. Use of EGF added to the culture medium by these cells paralleled the receptor levels. Cross-feeding experiments among NRK, KNRK, and Ts cultures indicated that Ts cells at the permissive temperature and KNRK cells at both temperatures produced a heat-stable substance(s) that stimulated DNA synthesis in NRK cells independent of the presence of serum or EGF. Conditioned medium from the transformed cultures also significantly enhanced EGF binding to NRK cells. These studies demonstrated a correlation between the transformed phenotype and the receptor levels of a potent cell mitogen, EGF, which was readily reversible in the Ts cultures. In addition, cultures expressing the transformed phenotype produced material that did not compete for the EGF receptor but did enhance EGF binding, in contrast to other reports involving sarcoma virus-transformed cells. - 79-5749 Different Rat-derived Transforming Retroviruses Code for an Immunologically Related Intracellular Phosphoprotein. (Eng) Young, H. A. (Lab. Tumor Virus Genetics, Div. Cancer Cause and Prevention, NCI, Bethesda, MD 20205); Shih, T. Y.; Scolnick, E. M.; Rasheed, S.; Gardner, M. B. *Proc Natl Acad Sci USA* 76(7): 3523-3527; 1979.

Three distinct fibroblast-transforming retroviruses were isolated from rats. Two of these viruses, Kirsten murine sarcoma virus (Ki-MSV) and Harvey murine sarcoma virus (Ha-MSV), were isolated by experimental inoculation of mouse C-type viruses into rats. The third virus, rat sarcoma virus (RaSV), was isolated in cell culture by cocultivation of a cell producing rat C-type viruses and a Fischer rat cell transformed by 4-nitroquinoline. These three retroviruses code for a related intracellular phosphoprotein that is not a virion structural protein. Ki-MSV and Ha-MSV code for a phosphoprotein, p21. p21 was identified with antisera prepared by transplantation in rats of syngeneic Ha-MSV- or Ki-MSV-transformed nonproducer cells. RaSV apparently codes for the phosphoprotein p29, which shares immunological determinants and common V-8 protease-generated peptides with the p21 of Ha-MSV. The data suggest that RaSV has acquired genetic information with similar coding capacity to some rat genetic information in the mouse-rat recombinant viruses Ki-MSV and Ha-MSV. Based on data obtained for the p21 of a mutant of Ki-MSV temperature-sensitive for the maintenance of transformation, it is suggested that the gene in RaSV that codes for p29 is also required for the maintenance of RaSV-induced fibroblast transformation. (28 refs)

- 79-5750 Presence of Virus-specific DNA Sequences in Murine Type C Viruses. (Eng) Byers, M. J. (La Jolla Cancer

Res. Foundation, Box 1376, La Jolla, CA); Avery, R. J.; Boaz, J.; Kohne, D. E. *J Gen Virol* 43(3): 611-621; 1979.

Total nucleic acids prepared from the Moloney and Rauscher leukemia viruses and the Kirsten leukemia/sarcoma virus complex were found to contain virus-specific DNA (vsDNA) in addition to genomic RNA. This vsDNA was at least partially double-stranded, and it was present within the virus core particle. Data obtained from studies of the extent of hybridization, hybridization kinetics, and thermal stability indicated that the DNA isolated from the virus was greatly enriched in vsDNA relative to that from virus-infected cells. Radioactive complementary DNA (cDNA) produced by the endogenous virus reverse transcriptase was used to detect these vsDNA sequences. In several cases, the cDNA preparations were reacted with purified virus RNA at low RNA:DNA ratios, and the hybridizing fraction was used to detect vsDNA. This selected cDNA reacted $\geq 85\%$ with homologous virus RNA with the kinetics of hybridization expected for a virus RNA:cDNA reaction of c-type RNA complexity. Thus, it is highly unlikely that the cDNA reacting with the virion DNA represented anything but vsDNA. The different cDNA's reacted 20%-60% with their respective virion DNA preparations. The reason for the considerable variation in the extent of reaction of the cDNA with the virion DNA is not known. It is possible that each different extent of reaction is a consistent feature of each different virus type. The origin of the vsDNA present in virion DNA is not known. Proviral DNA sequences may somehow be preferentially included in the virus during assembly of the virus in the cell. Alternatively, the vsDNA may be synthesized after virus assembly by the action of reverse transcriptase on the virion RNA. The biological role of vsDNA is not known, but an interesting speculation is that it is somehow involved in cell transformation. (18 refs)

79-5751 Purification of Protein Kinase of Mouse Sarcoma Virus and Its Effect on Reverse Transcriptase Activity. (Eng) Rokutanda, M. (Dept. Biochemistry, Tokyo Metropolitan Inst. Medical Science, 3-18-22 Honkomagome, Bunkyo-ku, Tokyo 113, Japan); Maeda, Y. Y.; Takahama, S. *Biochem Biophys Res Commun* 88(4): 1322-1328; 1979.

A protein kinase associated with purified virions of Moloney sarcoma virus (MSV) was purified by ion-exchange chromatography and separated from reverse transcriptase by poly A-Sepharose column chromatography. The reverse transcriptase of MSV was activated 1.6- to 3.5-fold upon incubation with ATP and protein kinase. The reverse transcriptase was activated by protein kinase as a result of phosphorylation, as confirmed by polyacrylamide gel electrophoresis. It is suggested that phosphorylation is one of the mechanisms that regulates the reverse transcriptase activity of MSV. (9 refs)

79-5752 RNA-directed DNA Synthesis in Moloney Murine Leukemia Virus: Interaction Between the Primer tRNA and the Genome RNA. (Eng) Peters, G. (Imperial Cancer Res. Fund Labs., Lincoln's Inn Fields, London WC2A 3PX, England); Dahlberg, J. E. *J Virol* 31(2): 398-407; 1979.

The interaction between transfer RNA^{Pro} (tRNA^{Pro}) and Moloney murine leukemia virus (M-MuLV) genome RNA was examined. Initiation of RNA-directed DNA synthesis in virions of M-MuLV required a cellular tRNA^{Pro} as primer. The site(s) on the M-MuLV genome RNA at which functional primer molecules were bound and at which purified tRNA^{Pro} hybridized was located near (within

20%) the 5' end of the genome. A relatively stable duplex (50% dissociation occurred at 76 C) was formed between the amino acid acceptor stem of the tRNA^{Pro} and a complementary sequence in the M-MuLV 35S RNA. The interaction involved 19 base pairs, extending from the penultimate nucleotide at the 3' end of the tRNA^{Pro} but apparently not including the 3'-terminal adenosine residue. In most respects, the interaction between primer and template in M-MuLV paralleled the situation in the avian leukosis-sarcoma viruses. (36 refs)

79-5753 Interactions of Retroviruses with Chemical Carcinogens. I. Noncovalent Binding of Unactivated Polycyclic Aromatic Hydrocarbons. (Eng) Harris, R. M. (Worcester Foundation Experimental Biology, Shrewsbury, MA 01545); Kupfer, D.; Luftige, R. B. *Virology* 97(1): 42-54; 1979.

The noncovalent binding of three carcinogenic polycyclic aromatic hydrocarbons (PAH's), benzo(a)pyrene, 3-methylcholanthrene, and 7,12-dimethylbenz(a)anthracene, to retroviruses (RV's) was quantitated using a rate zonal centrifugation assay, and the effects of the binding on a RV specific function, reverse transcription, were determined. The binding level for the enveloped RV's was much higher than that found for nonenveloped viruses (2.5- to 40-fold greater), such as bacteriophage T4 and adenovirus type 5. There was no special affinity of PAH compounds for RV's, as compared with another enveloped virus, Sindbis virus, and there was no binding to viral glycoproteins (type-specific antigens). These results suggest that the binding is best interpreted as partitioning of the hydrophobic PAH compounds between viral envelope lipids and the surrounding aqueous buffer. This interpretation is supported by the temperature and salt dependence of the binding. Using isolated retroviral cores, it was also found that there is a relatively small, but significant, level of binding of benzo(a)pyrene to retroviral cores. Further, the noncovalent binding of benzo(a)pyrene to Rauscher leukemia virus inhibits the RNA-dependent DNA polymerase activity. The inhibition requires preincubation of the virus and PAH, ie, the formation of noncovalent virus-PAH complexes, and it is consistent with a non-competitive model of enzyme inhibition with an inhibition constant, K_i , of about 40 μM . (34 refs)

79-5754 Radioimmunoassay Determination of Two Main Cross-reacting Viral Antigens During Radiation and Rauscher Induced Leukemias. (Eng) Sassen, A. (Dept. Radiobiology, CENSCK, 2400, Mol, Belgium); Plaetse, F. V.; Janowski, M.; Maisin, J. R. *Biomedicine* 30(3): 147-155; 1979.

The two main cross-reacting viral antigens produced during the evolution of radiation(RadLV)- and Rauscher leukemia virus (RLV)-induced leukemias in rats and mice were studied by radioimmunoassay. The p30 proteins from RLV and an RadLV derived from serial passages in rats [RadLV(rat)] were serologically indistinguishable, and they represented approx 15% of the total viral proteins in both cases. The gp70 proteins from RLV and RadLV(rat) showed partial identity based on competition curves. In C57Bl mice with leukemia induced by x-irradiation or by RadLV derived from serial passages in mice (RadLV-RS), the serum p30 level increased slightly during the course of the two leukemias. Gp70-related antigen (gp70-ra) was present in high concentrations in the serum 2-3 wk after treatment, especially in mice treated with RadLV-RS. In the spleens and lymph nodes of the RadLV-RS mice, the p30 level increased markedly and reached higher levels than did the gp70-ra; the reverse was usually observed

in the spleens and thymuses of RadLV mice. In Balb/c mice inoculated with RLV, the serum p30 level increased in parallel with spleen wt. The gp70 concentration did not show such a rapid increase. During RadLV(rat)-induced leukemia, large amounts of p30 and, to a lesser extent, gp70-ra were found in the tissues. Natural antibodies against the RLV and gp70 antigens were not found. The catabolic degradation of labeled RLV gp70 was similar in normal and leukemic mice. (40 refs)

- 79-5755 Glycopeptides of Murine Leukemia Viruses. I. Comparison of Two Ecotropic Viruses. (Eng) Kemp, M. C. (Dept. Microbiology, Univ. Alabama Medical Center, Birmingham, AL 35294); Basak, S.; Compans, R. W. *J Virol* 31(1): 1-7; 1979.

The glycopeptides obtained by pronase digestion of two ecotropic strains of murine leukemia virus (MuLV) were compared by gel filtration. Four different glycopeptide size classes, designated G₁, G₂, G₃, and G₄ with mol wts of approx 5,100, 2,900, 2,200, and 1,500, respectively, were shown to be associated with Rauscher MuLV virions grown in JLS-V9 cells. Various sugar precursors, including glucosamine, galactose, fucose, and mannose, were incorporated into G₁ and G₂, suggesting that these are complex (type I) glycopeptides. The two smaller glycopeptide size classes, G₃ and G₄, were shown to be mannose-rich (type II) glycopeptides. G₄ was more sensitive to digestion with endo- β -N-acetylglucosaminidase H than G₃, suggesting that the core of G₃ may contain fewer mannose residues. Glycopeptides of the same size class as G₁ and G₂ were associated with both Rauscher MuLV and AKR-MuLV grown in I116A (mouse embryo) cells. Previous studies have shown that gp52, a proteolytic cleavage product of gp70, possesses primarily G₁ glycopolypeptides and that gp52 is more highly sulfated than gp70. G₁ was approx twofold more highly sulfated than G₂; thus the observed difference in sulfation of gp52 is explained. The usually large size of G₁ suggested that infection with MuLV may alter the host cell glycosylation pattern. To test this possibility, glycopeptides from Sindbis virions grown in uninfected and Rauscher MuLV-infected JLS-V9 cells were compared, and no differences were observed. G₁ was not detected in Sindbis virions, indicating that acquisition of G₁ depends on properties of the virus-coded polypeptide backbone of the gp70 molecule. (36 refs)

- 79-5756 Quantitative Changes in Spleen Cellularity in Mice Inoculated with Rauscher Leukemia Virus and *Brucella abortus*. (Rus) Belianchikova, N. I. (Lab. Tumor Virology, Cancer Res. Center, Moscow, USSR); Veskova, T. K.; Chimishkian, K. L.; Trubcheninova, L. P.; Svet-Moldavskii, G. Ia.; Gusovskaia, I. M. *Vopr Onkol* 25(6): 76-80; 1979.

The effect of combined infection with Rauscher leukemia virus (RLV) and *Brucella abortus* (BA) was studied in BALB/c mice. Animals were inoculated with RLV (10³ median infective dose, iv) and, on the next day, with live *Brucella* vaccine (10⁹ microbes in 0.2 ml soln). The mice were sacrificed at various times after infection, and spleen cellularity was determined. The total spleen cellularity in mice exposed to RLV + BA was significantly greater than that in controls infected with RLV alone. The increase was caused by BA-induced proliferation of the lymphoid tissue and by the development of the leukemic process. Administration of BA inhibited the proliferation of leukemic erythroblasts and normalized the count of megakaryocytes and plasma cells. (11 refs)

- 79-5757 Propagation and Characterization of a C-Type Virus from a Rhabdomyosarcoma of a Corn Snake. (Eng) Clark, H. F. (Wistar Inst. Anatomy and Biology, 36th St. at Spruce, Philadelphia, PA 19104); Andersen, P. R.; Lunger, P. D. *J Gen Virol* 43(3): 673-683; 1979.

Electron microscopy previously demonstrated the presence of budding C-type viruses in an embryonic rhabdomyosarcoma of a corn snake (*Elaphe guttata*). More recently, virus [corn snake retrovirus (CSRV)] was recovered from rhabdomyosarcoma tissue suspensions inoculated onto cells of a rattlesnake fibroma cell line or cultures of early passage cells derived from a normal rattlesnake heart or kidney. Attempts to cultivate the virus in other reptilian cell systems were unsuccessful. The virus was classified as a retrovirus on the basis of electron microscope observations of fine structure and morphogenesis and the demonstration of virion-associated reverse transcriptase and a buoyant density of 1.16. Polypeptide analysis of CSRV by polyacrylamide gel electrophoresis revealed the presence of five major polypeptides: three had mobility analogous to that of structural polypeptides of viper retrovirus (VRV), but two polypeptides, one of mol wt approx 16,000 and a glycoprotein of mol wt approx 72,000, were unique. Antigenic comparison of CSRV and VRV by agar gel immunodiffusion revealed that CSRV possesses a major antigenic determinant that is different from that of VRV. CSRV propagated in rattlesnake fibroma cells was slowly cytopathic for rattlesnake heart and kidney cells in vitro. (33 refs)

- 79-5758 Involvement of Different Exogenous Feline Leukemia Virus Subgroups in the Generation of Independent Feline Sarcoma Virus Isolates. (Eng) Robbins, K. C. (Lab. Cellular and Molecular Biology, NCI, Bethesda, MD 20014); Barbacid, M.; Porzig, K. J.; Aaronson, S. A. *Virology* 97(1): 1-11; 1979.

Complementary DNA (cDNA) probes synthesized from clonal isolates of three feline leukemia virus (FeLV) subgroups were used to study the genetic relatedness of these subgroups. The extent of cross homology detected between the genomes of the three strains ranged from 78% to 88%. The thermal stabilities of heterologous viral cDNA-RNA hybrids were significantly lower than those of homologous hybrids. None of the FeLV subgroup cDNA's was hybridized >50% by normal cat cellular DNA. The thermal stability values of hybrids formed between FeLV-A, -B, or -C-infected cat cellular DNA and the homologous FeLV viral cDNA were 86.4, 84.9, and 86.4 C, respectively. The data indicate that none of the known FeLV subgroups was fully represented as an endogenous virus of cat cells. The SM isolate of feline sarcoma virus (FeSV) contained a larger fraction of FeLV genetic information than either the GA or ST isolates of FeSV, and the thermal stability data suggested that FeLV-B was the source of the FeLV nucleotide sequences in SM-FeSV. In spite of a very high degree of immunologic relatedness among the respective gag gene-coded p15 and p12 proteins of the FeLV subgroups, type-specific determinants could be detected. The pattern of reactivity of each FeLV variant in a series of p15 typing immunoassays served to distinguish the variants. Data derived from empirically devised FeLV p15 typing assays suggested that a different FeLV was involved in the generation of each of the three known isolates of FeSV. (58 refs)

- 79-5759 Influence of Adrenal Corticosteroids on the Susceptibility of Cats to Feline Leukemia Virus Infection.

(Eng) Rojko, J. L. (Dept. Veterinary Pathobiology, Ohio State Univ., 1925 Coffey Road, Columbus, OH 43210); Hoover, E. A.; Mathes, L. E.; Krakowka, S.; Olsen, R. G. *Cancer Res* 39(9): 3789-3791; 1979.

The effect of a synthetic adrenocorticosteroid hormone, methylprednisolone acetate (MPA), on resistance to feline leukemia virus (FeLV) infection and leukemogenesis in adult cats was determined. The natural resistance of adult specific-pathogen-free cats to FeLV was abrogated by treatment of the cats with 5-50 mg/kg MPA im, prior to either po-nasal or ip inoculation of FeLV. Persistent viremia was induced in 18/22 MPA-treated cats vs 1/9 age-matched control cats. MPA-treated FeLV-inoculated cats developed prolonged lymphopenia (2-8 wk postinoculation) and a delayed antibody response to feline oncornavirus-associated cell membrane antigen. The distribution of FeLV group specific antigen in tissues of MPA-treated, FeLV-inoculated cats suggested that corticosteroids enhanced susceptibility to FeLV by impairing early viral containment in the reticuloendothelial and lymphoid tissues. (23 refs)

79-5760 Genetic Relatedness of Mammalian Type C Helper and Replication-defective Transforming Viruses.

(Eng) Stephenson, J. R. (Lab. RNA Tumor Viruses, NCI, Bethesda, MD 20014); Khan, A. S.; Deobagkar, D. N.; Reynolds, F. H.; Reynolds, R. K.; Sacks, T. L. In: *Biological Markers of Neoplasia: Basic and Applied Aspects*. Proceedings of an international conference held 22-26 May 1978, Leesburg, VA. Ruddon, E. W., ed. (New York; Elsevier): 590 pp.; 95-113; 1978.

Cells nonproductively transformed by diverse replication-defective transforming viruses were analyzed for the expression of C-type helper virus proteins. Cell lines nonproductively infected by various mammalian transforming virus isolates express different numbers of C-type viral *gag* gene-coded proteins in a progressive fashion from the 5' to the 3' end of the *gag* gene. In cells transformed by feline sarcoma virus (FeSV) or by Abelson murine leukemia virus (A-MuLV), the two amino terminal *gag* gene-coded proteins, p15 and p12, are initially expressed in the form of polyproteins of around 110,000-130,000 mol wt. A similar, although somewhat smaller (100,000-110,000 mol wt), p15-p12-containing polyprotein has also been found in mink cells transformed by the recently described T8 isolate of the mink cell focus-forming MuLV. The viral-coded nature of the A-MuLV polyprotein is established by in vitro translation. These high-mol wt precursors are highly acidic; they undergo posttranslational cleavage, giving rise to a 25,000-mol wt intermediate cleavage product containing p15 and p12, and they lack detectable immunologic cross-reactivity with p30, p10, gp70 or reverse transcriptase. In the feline system, a 60,000-mol wt cleavage product of the initial 110,000- to 130,000-mol wt precursor has been shown to possess immunologic cross-reactivity with the tumor-specific feline oncornavirus-associated cell membrane antigen, which suggests that this viral-coded protein contains transformation-specific sequences. (39 refs)

79-5761 Incorporation of HLA Antigens into the Envelope of RNA Tumor Viruses Grown in Human Cells. (Eng)

Azocar, J. (Dept. Microbiology, Harvard Univ. Sch. Public Health, 665 Huntington Ave., Boston, MA 02115); Essex, M. *Cancer Res* 39(9): 3388-3391; 1979.

Human lymphoblastoid cell lines productively infected with feline leukemia virus (FeLV) were studied to determine whether human

cell antigens are incorporated into virions. Fetal bovine sera plus rabbit complement or undiluted preinoculation rabbit sera plus complement were not cytotoxic for the infected or uninfected RPMI-8042 or HSB-2 cell lines. Rabbit sera collected 1 wk after final immunization with RPMI-8042 were cytotoxic for RPMI-8042 cells, and sera collected 1 wk after final immunization with HSB-2 cells were cytotoxic for HSB-2 cells. All of the FeLV-infected cells were positive for membrane fluorescence with goat anti-FeLV:fluorescein isothiocyanate (FITC). Antigenic cocapping was observed in the same location when the cells were treated with the approximate anti-HLA sera and anti-human IgG: rhodamine. Absorption of rabbit antisera produced against HSB-2 cells with uninfected HSB-2 cells greatly reduced the neutralizing activity of the antiserum as directed to FeLV grown in the same cells. The same effect was observed with the RPMI-8042 line. When antiserum against FeLV-infected HSB-2 cells was absorbed with uninfected HSB-2 cells, this antiserum retained neutralizing activity for FeLV. Antisera to the A determinant A1 had a greater effect in neutralizing virus produced by HSB-2 than did the antisera to the B determinant B12. When virus derived from the RPMI-8042 line was tested with antisera to HLA-A29 or HLA-A1 (which are present in these cells) plus rabbit complement, a 40%-59% reduction in infectivity was obtained compared with a control treatment using either antiserum to an unrelated antigen, normal serum, or complement alone. (13 refs)

79-5762 In Vitro Transformation by Bovine Papilloma Virus. (Eng) Meischke, H. R. (Bureau Animal Health, Dept. Primary Industry, Canberra, Australia). *J Gen Virol* 43(3): 473-487; 1979.

Bovine papilloma virus (BPV) was investigated with regard to such parameters of cell transformation as the range and sources of transformation permissive cells, the precision and sensitivity of transformation assays, the inhibition of in vitro transformation, and the time-temperature inactivation of BPV. BPV from fibropapilloma consistently transformed cell cultures from fetal bovine palate, conjunctiva, and vascular meninges, as well as skin cultures from near-term fetuses. When cells were infected in suspension, complete adsorption of BPV took 3-4 days, while when the cells were infected as a monolayer, adsorption took up to 7 days. The transformed cultures demonstrated a consistent increase in longevity when compared with controls (2.5- to 3-fold increase in lifespan). No colonies were formed by transformed cells during a 4-wk observation period after suspension in 0.3% agar. There was a considerable variation in the optimal time determined for reading assay plates between the cell cultures. When cells were infected in suspension, wisps first appeared 7-10 days later; when they were infected as monolayers, wisps first appeared after 11-14 days. Transformation was induced in the four most studied cultures (two skin and one each meninges and conjunctiva) by BPV extracted from cutaneous, teat, and alimentary fibropapilloma of cattle. No significant differences were observed between titers of pasteurized and untreated virus isolates. A 10-fold reduction in transformation titer occurred after 4 hr when one fibropapilloma-derived virus isolate was held at 60 C for various lengths of time. All detectable activity was lost when the same isolate was held at 80 C for 30 min. BPV-like viruses were found in milk samples from six separate dairies. It is shown that transformation inhibition activity may be adsorbed from high titer sera using BPV-induced tumor cells or in vitro transformed cells, but not with various virus suspensions. (22 refs)

79-5763 Amino-terminal Sequence of Bovine Leukemia Virus Major Internal Protein: Homology with Mammalian

Type C Virus p30 Structural Proteins. (Eng) Oroszlan, S. (Biological Carcinogenesis Program, Frederick Cancer Res. Center, Frederick, MD 21701); Copeland, T. D.; Henderson, L. E.; Stephenson, J. R.; Gilden, R. V. *Proc Natl Acad Sci USA* 76(6): 2996-3000; 1979.

The amino acid composition, the COOH-terminal amino acid, and the NH₂-terminal amino acid sequence of the first 55 residues of the major internal structural protein, p24, of bovine leukemia virus (BLV) were determined to define the similarity of BLV to other mammalian retroviruses. The compositional data and the results of end-group analysis revealed that, although BLV p24 is chemically distinct, it more closely resembles the p30 structural proteins than the other *gag* gene products of mammalian retroviruses. BLV p24 shares the common NH₂-terminal proline and COOH-terminal leucine but lacks the common prolylleucylarginine tripeptide and the larger conserved region found near the NH₂ terminus of all mammalian C-type viral p30's. Alignment of the amino acid sequence of BLV p24 with the previously determined sequence of feline leukemia virus p27 revealed a statistically significant sequence homology. A more distant relationship was found between BLV p24 and other mammalian p30's. The finding of a definite sequence homology between BLV p24 and mammalian C-type virus p30's clearly establishes the origin of these contemporary viral proteins from common progenitor genes. 79-5764 Elevated Titer of Antibodies to Simian Sarcoma Virus Envelope Antigen (gp70) and Normal Response to Influenza Virus in Untreated Danish Hodgkin's Patients. (Eng) Ebbesen, P. (Dept. Tumor Virus Res., Univ. Copenhagen, Copenhagen, Denmark); Due, C.; Hesse, J.; Kurth, R.; Noble, G. R.; Gallagher, R.; Voller, A.; Jensen, G. *Int J Cancer* 24(1): 1-5; 1979.

Tests for serum antibodies to Epstein-Barr virus (EBV), six strains of influenza virus, and simian sarcoma virus/simian sarcoma-associated virus [SSV(SSAV)] antigens were performed in 130 untreated Danish Hodgkin's disease (HD) patients and paired with age- and sex-matched controls. HD sera showed significantly elevated titers against EBV and an increased incidence and increased mean titer of antibodies to the envelope glycoprotein (gp 70) of SSV(SSAV), whereas testing against the influenza viruses revealed no differences between HD patients and controls. A focus-reduction assay demonstrated a low incidence in HD patients and controls of sera with neutralizing effects against SSV(SSAV) and the baboon C-type virus component of the human HL-23 virus complex, which seemed to be coupled to the HL-A antigen W19. (44 refs)

79-5765 Viral Etiology of Osteomyelofibrosis, a Preleukemic Syndrome of Childhood. (Ger) Chandra, P. (Abteilung für Molekularbiologie, Zentrum der Biologischen Chemie, Theodor-Stern-Kai 7, 6 Frankfurt (Main) 70, W. Germany); Steel, L. K.; Laube, H.; Kornhuber, B. *Klin Paediatr* 191(2): 156-174; 1979.

Three cellular DNA polymerases and a reverse transcriptase (RT) were isolated from the surgically removed spleen of a patient with osteomyelofibrosis. This is the first report of the identification and characterization of a tumor-specific enzyme from the tissue of a patient with a preleukemic syndrome. The mol wt of the RT was 70,000, and the mol wts of the polymerases were 40,000, 150,000,

and 100,000. The RT was identified by its RNase sensitivity and its ability to transcribe the heteropolymer region of 70S RNA from Rauscher murine leukemia virus (R-MuLV). The conclusion that RT was isolated was strengthened by the observations that poly C.oligo dG stimulated the enzyme activity, and the RT's from simian sarcoma and Gibbon ape leukemia viruses showed several similarities to the new RT in serological tests. The RT's from R-MuLV and avian myeloblastosis virus produced a weak cross-reaction with the new RT in immunological tests, but the RT from the membrane of human acute lymphatic leukemia cells produced a strong reaction. The three DNA polymerases that were isolated did not produce these reactions. The strong cross-reaction with the RT from human leukemia cells indicates that antibodies to this enzyme could be produced and used to detect leukemia cells in patients before the appearance of clinical signs of leukemia. 79-5766 Characterization of Infection and Replication of Mason-Pfizer Monkey Virus in Human Cell Cultures. (Eng) Fine, D. L. (Biological Carcinogenesis Program, Frederick Cancer Res. Center, Frederick, MD 21701); Clarke, G. C.; Arthur, L. O. *J Gen Virol* 44(2): 457-469; 1979.

The infection and replication of the Mason-Pfizer monkey virus (MPMV) in cells of the human rhabdomyosarcoma cell line, A204, were studied. A204 cultures inoculated with 10⁻⁴ to 10⁻⁶ virus dilutions did not express reverse transcriptase (RT) until after subculturing, but productive infection could be accomplished at virus particle (VP) input multiplicities as low as approx 6 x 10⁻² VP/cell. MPMV expression was stable with continuous culture passage and after freeze-thawing, but virus infectivity was destroyed by UV irradiation and by sonication. MPMV replication and production in A204 cultures was cell-cycle-dependent, the highest levels of RT activity coinciding with the peak of mitosis and early G₁. The release of MPMV from infected cells appeared to be dependent upon the passage of cells through mitosis. Inhibition of MPMV production in cells arrested in mitosis appeared to be due to a limiting step prior to virus maturation. The information gained in this study was applied in the isolation of MPMV-like viruses from naturally and experimentally infected Rhesus monkeys following co-cultivation of tissues with A204 cell cultures. 79-5767 Physicochemical Properties and Restriction Maps of Simian Adenovirus Type 38 DNA. (Eng) Dimitrov, D. H. (Lab. Biochemistry, D. I. Ivanovsky Inst. Virology, Moscow D-98, USSR); Dubitchov, A. G.; Naroditsky, B. S.; Dreizin, R. S.; Tikchonenko, T. I. *J Gen Virol* 44(1): 69-80; 1979.

The physicochemical properties and restriction endonuclease maps of simian adenovirus type 38 (Ad38) DNA were studied. The sedimentation constant of Ad38 DNA was estimated to be 31.6S. The intrinsic viscosity averaged 86.5 deciliters/g, and the length of the molecule was 10.6 μm. The av mol wt was 21.5 x 10⁶, which agreed well with the value derived from the length of the molecule (21.4 x 10⁶) and with the value of 21.2 x 10⁶ determined by the relative electrophoretic mobility of the DNA fragments produced by restriction endonucleases *EcoRI*, *SalI*, and *BglII*. The buoyant density of the DNA in cesium chloride and cesium sulfate was 1.7185 and 1.4295 g/ml, respectively. The melting temperature of the DNA was 93.5 °C, and the guanine-cytosine content was 59.3%. *BglII* cleaved the Ad38 DNA at three sites, producing four fragments with mol wts of 9.3 (A), 5.6 (B), 3.3 (C), and 2.9 (D) x 10⁶, respectively. After treatment with *EcoRI* and *SalI*, the DNA was cleaved into five and six fragments, respectively. The mol wts

of the *Eco*RI fragments were 8.2 (A), 6.5 (B), 4.0 (C), 1.27 (D), and 1.07 (E) $\times 10^6$, respectively, and those for the *Sa*II fragments were 6.5, 5.4, 4.2, 2.8, 2.5, and 0.25 $\times 10^6$, respectively. The sequence of fragments within the Ad38 DNA molecules was BDCA for *Bgl*II, and BCEAD for *Eco*RI. (18 refs)

79-5768 *Herpesvirus papio*: State and Properties of Intracellular Viral DNA in Baboon Lymphoblastoid Cell Lines. (Eng) Falk, L. (Dept. Tumor Biology, Karolinska Inst., S-104-01 Stockholm, Sweden); Lindahl, T.; Bjursell, G.; Klein, G. *Int J Cancer* 24(1): 75-79; 1979.

The physical state of the viral DNA in lymphoblastoid cell lines derived from baboon species that harbor *Herpesvirus papio* (HVP), an indigenous B-lymphotropic virus of baboons, was investigated. HVP shares cross-reacting viral capsid and early antigens with Epstein-Barr virus (EBV), and HVP DNA and EBV DNA show partial sequence homology. EBV-specific complementary RNA was used as a probe to investigate the physical state of the HVP DNA component in baboon lymphoblastoid cells after fractionation of cellular DNA by density gradient centrifugation. Five virus-producing cultures contained both free and integrated HVP DNA sequences, but one nonproducing cell line had two or three viral genome equivalents per cell in apparently integrated form. Further analysis of one virus-producing line showed that the free HVP DNA fraction was composed of both linear and circular viral DNA. Contour length measurements of HVP circular DNA molecules by electron microscopy revealed that they were similar in length to the EBV circular DNA present in human lymphoblastoid cells. (17 refs)

79-5769 Familial Herpes Simplex Infection Associated with Activation of the Complement System. (Eng) Kapadia, A. (Memorial Sloan-Kettering Cancer Center, 1275 York Ave., New York, NY 10021); Gupta, S.; Good, R. A.; Day, N. K. *Am J Med* 67(1): 122-126; 1979.

The peripheral blood lymphocytes from a female patient with severe recurrent herpes infection responded by proliferation to herpes simplex antigen but failed to produce leukocyte migration inhibition factor. Herpes simplex antibody titers increased during active infection. Total hemolytic complement, the third, fifth, sixth, and seventh components of complement, and factor B were dramatically reduced; the first, second, and fourth complement components were within normal limits. In members of her family that had a history of recurrent herpes simplex, one or more of complement components 5, 6, or 7 was reduced. (24 refs)

79-5770 Separation and Characterization of Herpes Simplex Virus Type 1 Immediate-Early mRNA's. (Eng) Watson, R. J. (Lab. Molecular Virology, NCI, Bethesda, MD 20205); Preston, C. M.; Clements, J. B. *J Virol* 31(1): 42-52; 1979.

Polyadenylated immediate-early transcripts of herpes simplex virus type 1, made in BHK cells infected and maintained in the presence of cycloheximide, were separated on denaturing agarose gels containing methyl mercuric hydroxide. Three virus-specific messenger (mRNA) RNA bands of estimated sizes 4.7, 3.0, and 2.0 kilobases (kb) were detected, and these mRNA's were mapped on the virus genome and also used to direct protein synthesis *in vitro*. The 4.7- and 3.0-kb mRNA's hybridized predominantly to certain

DNA fragments which are located in the short and long repetitive regions of the genome, respectively, whereas the 2.0-kb mRNA mapped to three discrete regions of the virus DNA. *In vitro* translation of these separated mRNA size classes indicated that the 3.0-kb mRNA specified the synthesis of virus polypeptide Vmw 110, whereas the 2.0-kb mRNA's specified Vmw 68, 63, and 12. The synthesis of small amounts of Vmw 175 was specified by the 4.7-kb mRNA. In contrast with the mRNA's which specify these other immediate-early polypeptides, that specifying Vmw 12 is much larger than required for its coding sequences. (25 refs)

79-5771 Properties of Herpes Simplex Virus DNA Polymerase and Characterization of Its Associated Exonuclease Activity. (Eng) Knopf, K. W. (Institut für Virusforschung, Deutsches Krebsforschungszentrum, Heidelberg, W. Germany). *Eur J Biochem* 98(1): 231-244; 1979.

The large-scale purification of herpes simplex virus type 1 (HSV-1) DNA polymerase is described, along with the characterization of the exonuclease activity associated with this enzyme. HSV-1 DNA polymerase was isolated from infected African green monkey kidney cells. After DNA-cellulose chromatography, the enzyme showed a specific activity of 48,000 units/mg protein. Three major single polypeptides with mol wts of 144,000, 74,000, and 29,000 were copurified with the enzyme activity at the DNA-cellulose step. By its chromatographic behavior and by template studies, the HSV DNA polymerase activity was clearly distinguishable from cellular α , β , and γ DNA polymerase activities. Two exonucleolytic activities were found in the DNA-cellulose enzyme preparation. The main exonucleolytic activity, which degraded both single- and double-stranded DNA to deoxynucleoside 5'-monophosphates, was separated by subsequent velocity sedimentation. The remaining exonucleolytic activity was not separable from the HSV DNA polymerase by several chromatographic steps and by velocity sedimentation at high ionic strength. This novel exonuclease and HSV DNA polymerase were equally sensitive to phosphonoacetic acid and Zn^{2+} ions, inhibitors of the viral polymerase. Similar to the 3'- to 5'-exonuclease of prokaryotic DNA polymerases and mammalian DNA polymerase δ , the HSV polymerase-associated exonuclease catalyzed the removal of 3'-terminal nucleotides from the primer/template as well as the template-dependent conversion of deoxynucleoside triphosphates to monophosphates. (33 refs)

79-5772 Modulation of Herpes Simplex Virus Replication in Adenovirus Transformed Cells. (Eng) Stenberg, R. (Dept. Microbiology, Univ. Colorado Medical Center, Denver, CO 80262); Spector, D.; Pizer, L. *J Gen Virol* 44(2): 297-309; 1979.

The ability of herpes simplex virus type 1 (HSV-1), strain HF, to replicate in adenovirus type 5 (Ad 5)-transformed cells was examined, in order to determine whether the presence of an integrated adenovirus genome or the cell type plays the major role in restricting the ability of HSV to replicate. Ad-transformed human and hamster cells maintained their permissiveness for HSV replication, while rat cells were either nonpermissive or showed a strong temperature dependence for the production of infectious HSV. One line of Ad 5-transformed rat cells, 107, allowed HSV to replicate at 34 C but not at 37 C and was examined in detail. At 37 C, virus-specific DNA synthesis was greatly reduced, but all of the late virus structural proteins could be observed after sodium dodecyl sulfate-polyacrylamide gel electrophoresis. Shut-off of host macromolecular synthesis was less efficient after HSV infec-

tion of 107 cells than after infection of more permissive cells, such as the nontransformed rat embryo fibroblast (REF) line. The data show that interactions between HSV and the host cell are perturbed when the cell is transformed by Ad 5 and that this disruption reduces the yield of virus progeny. Whether endogenous viruses influence the fate of HSV infection and the establishment and maintenance of latency should be examined. (23 refs)

79-5773 Presence of Herpes Simplex Virus Type 2 DNA in Hamster Cells Oncogenically Transformed by Ultraviolet-inactivated Virus. (Eng) Bibor-Hardy, V. (Institut du Cancer de Montreal, Centre Hospitalier Notre-Dame, 1560 est, rue Sherbrooke, Montreal, Quebec H2L 4M1, Canada); Kessous, A.; Simard, R. *Can J Biochem* 57(6): 867-872; 1979.

Herpes simplex virus type 2 (HSV-2) DNA was detected by molecular hybridization techniques in Syrian hamster embryo fibroblast cells transformed by UV-irradiated virus. At early passages after the cells were cloned in soft agar, about 40% of the HSV-2 genome was present in all the transformed cell lines at one to six copies per cell. In cell lines derived from tumors induced by these cells, the same percentage of the HSV-2 genome was found with a more uniform number of copies (between 2 and 3). Thus, the presence of viral DNA seems to be necessary for maintenance of the transformed state in these cell lines. (31 refs)

79-5774 Production of Tubular Structures in Vero Cells Infected with Herpes Simplex Virus Type 2: Effects of Ultraviolet Light Irradiation and Antimetabolites. (Eng) Iwasaka, T. (Dept. Microbiology, Sch. Medicine, Kyushu Univ., Fukuoka 812, Japan); Oda, H.; Mori, R.; Miyazono, J.; Nagafuchi, S. *J Gen Virol* 44(1): 57-67; 1979.

The nature of the tubular or filamentous structures specifically found in herpes simplex virus type-2 (HSV-2)-infected cells was investigated by determining the multiplication of HSV-2 in Vero cells cultured in the presence of varying concentrations of cytosine arabinoside (Ara-C) and cycloheximide (CH), inhibitors of DNA synthesis and protein synthesis, respectively. At 60 µg/ml, Ara-C inhibited the multiplication of HSV-2 by >99% and also prevented the appearance of tubular structures and virus particles in the nuclei of infected cells. Nevertheless, the synthesis of virus-specific surface antigens of HSV-2-infected Vero cells was not reduced, as revealed by the fluorescent antibody technique. On the other hand, 10 µg/ml CH inhibited the appearance of tubular structures and virus particles and the synthesis of virus-specific surface antigens by >99%. These observations strongly suggest that the appearance of tubular structures is one of the late events in virus multiplication. To measure the comparative genome size needed to produce membrane antigens, tubular structures, and infectious centers, the effect of UV inactivation of HSV-2 on these processes was studied. After UV irradiation, the capacity to induce tubular structures was inactivated at a slower rate than the capacity to form infectious centers, but at a faster rate than the capacity to induce surface antigens. Furthermore, more tubular structures could be induced by UV-inactivated virus than by nonirradiated virus, which was diluted to the same infectivity as the UV-irradiated virus. These results indicate that expression of the entire genome is not required for the production of tubular structures. (20 refs)

79-5775 Analysis of Chromosomes, Nucleic Acids, and Polypeptides in Hamster Cells Transformed by Herpes Simplex Virus Type 2. (Eng) Kessous, A. (Institut du

Cancer de Montreal, Centre Hospitalier Notre-Dame, 1560 est, rue Sherbrooke, Montreal, Quebec H2L 4M1, Canada); Bibor-Hardy, V.; Suh, M.; Simard, R. *Cancer Res* 39(8): 3225-3234; 1979.

Syrian hamster embryo fibroblasts were oncogenically transformed by UV-inactivated herpes simplex virus type 2, and data obtained from comparative studies of 2/18 clones isolated and their tumor derivatives are reported. Karyotype analysis revealed different chromosome patterns in the two clones and a tendency toward hypodiploidy in the tumor derivatives. All of these cell lines were shown by molecular hybridization to contain 40% of the HSV genome in several copies. The viral DNA sequence complexity was retained in the tumor derivatives, but a decrease in copy number was observed. Viral RNA's were detected by in situ hybridization in all lines tested. Viral antigens could be observed in these transformed cells by immunofluorescence. Finally, polypeptide analysis showed three reproducible differences between normal and transformed cells: (1) a polypeptide with a mol wt of 200,000 was detected in smaller quantities or not at all in the transformed cells; (2) a polypeptide with a mol wt of 84,000 was consistently observed in most transformed clones but not in normal cells; (3) a polypeptide with a mol wt of 42,500 was present only in transformed cells and their tumor derivatives. (46 refs)

79-5776 Studies Demonstrating the Immunological Identity of the Tumor-associated Antigen AG-4 with a Virion Envelope Protein. (Eng) Strnad, B. C. (Div. Comparative Medicine, Dept. Biochemistry and Biophysics, Johns Hopkins Univ. Sch. Medicine, Hygiene and Public Health, Baltimore, MD); Smith, M. F.; Aurelian, L. *IARC Sci Publ* 24(1): 203-213; 1978.

The immunological identity of the cervical tumor-associated antigen AG-4 is reviewed. Herpes simplex virus type 2 (HSV-2)-infected cell protein No. 10 (ICP 10) was purified by acrylamide gel electrophoresis and found to fix complement with IgM from AG-4 positive human sera. Preincubation of AG-4 antigen with Fab' from anti-ICP 10 completely blocked its ability to fix complement with AG-4 positive sera, thus demonstrating the immunological identity of ICP 10 and AG-4. IgG from anti-ICP-10 sera fixed complement with HSV-2, and their complement fixing potential for AG-4 was absorbed with virions. Autoradiography demonstrated that ICP 10 is an envelope protein, and AG-4 was shown to occupy a site on the envelope surface which is sterically removed from those involved in neutralization and infectivity. (11 refs)

79-5777 Characterization of a Tree Shrew Herpesvirus Isolated from a Lymphosarcoma. (Eng) Darai, G. (Institut für Medizinische Virologie, Universität Heidelberg, Im Neuenheimer Feld 324, 69 Heidelberg, W. Germany); Matz, B.; Schroder, C. H.; Flugel, R. M.; Berger, U.; Munk, K.; Gelderblom, H. *J Gen Virol* 43(3): 541-551; 1979.

Data are given on the isolation and characterization of a herpesvirus isolated from a lymphosarcoma culture of tree shrews (*Tupaia belangeri*) and termed *Tupaia* herpesvirus 2 (THV-2). Electron microscopy of THV-2 revealed the presence of virus particles with nucleocapsids of about 100 nanometers surrounded by large envelopes compatible with virions of the herpesvirus group. An extensive host range study revealed that *Tupaia* embryonic fibroblasts are the cells of choice for the efficient propagation of THV-2. This cell line was used for the continued propagation and

plaque assay of THV-2. The mol wt of the virus DNA was found to be 100×10^6 . The buoyant density of THV-2 was 1.724 g/ml. The DNA of THV-2 was compared with the DNA of herpes simplex virus (HSV) and with that of a herpesvirus isolated previously from apparently healthy tree shrews (THV-1) using the restriction endonuclease *EcoRI*. The cleavage pattern of THV-2 DNA resulted in DNA fragments that were different from those of HSV-1 DNA and from those of THV-1 DNA. (22 refs)

- 79-5778 Etiological and Clinical Data on Hemangiomas. (Hun) Frank, K. (Gyermekklinika, Orvostovábbképző Intézet, Budapest, Hungary). *Orv Hetil* 120(22): 1301-1302; 1979.

Cytomegalovirus (CMV) was found in the serum of a premature baby with hemangiomas and somatic and mental retardation. Immunoelectrophoresis revealed an elevated IgM level. The findings suggest a possible link between hemangiomas and CMV infection. In general, hemangiomas may be the angiopathic consequence of maternal infection. (17 refs)

- 79-5779 Mapping of Putative Transforming Sequences of EBV DNA. (Eng) Kieff, E. (Section Infectious Disease, Dept. Medicine, Univ. Chicago, Chicago, IL); Raab-Traub, N.; Given, D.; King, W.; Powell, A. T.; Pritchett, R.; Dambaugh, T. *IARC Sci Publ* 24(1): 527-552; 1978.

The linkage of restriction enzyme fragments of Epstein-Barr virus (EBV) DNA (B95-8 strain) has been determined. Two approaches are being employed to define which EBV DNA sequences are needed to initiate and maintain the transformation of lymphocytes to lymphoblasts capable of long-term growth in culture. The first approach is to determine the differences between the DNA of EBV strains which possess transforming capacity and the DNA of the HR-1 strain which cannot transform. The data indicate that EBV (HR-1) DNA lacks approximately 2.3×10^6 daltons of DNA contained largely in the *HsuI* B and *EcoRI* (J-K) and A fragments of EBV (B95-8) DNA and in the *EcoRI* A and *HsuI* B fragment of the W91 strain. The DNA common to *HsuI* B and *EcoRI* A fragments lies between 27 and 42×10^6 daltons from the *HsuI* A end of the molecule. This finding is compatible with the hypothesis that the inability of the HR-1 strain to transform is due to the absence of DNA needed for transformation. The second approach is to identify and map the DNA encoding polyadenylated viral RNA in cultures of reproductively infected cells which contain the EBV nuclear antigen (EBNA) and show no evidence of abortive or productive infection. Previous data have indicated that viral RNA species encoded by 5% of the viral DNA are adenylated and identified in the polyribosomes of reproductively infected cells. The data indicate that these RNAs are encoded primarily by the *HsuI* A (and to a lesser extent, B) fragment of EBV (B95-8) DNA. This would place the DNA encoding the viral RNA processed in reproductively infected cells adjacent to and possibly overlapping the small DNA segment deleted from the DNA of the nontransforming HR-1 strain. (27 refs)

- 79-5780 Sites of Sequence Variability in Epstein-Barr Virus DNA from Different Sources. (Eng) Rymo, L. (Dept. Clinical Chemistry, Gothenburg Univ., 40033 Gothenburg, Sweden); Lindahl, T.; Adams, A. *Proc Natl Acad Sci USA* 76(6): 2794-2798; 1979.

The intracellular Epstein-Barr virus (EBV) DNA present in virus-transformed cells was partly purified from 23 cell lines or biopsies of Burkitt's lymphoma, nasopharyngeal carcinoma, infectious mononucleosis, or healthy carrier origin. This DNA was cleaved into fragments (A-K) with mol wts between 1×10^6 and 30×10^6 with the restriction enzyme *EcoRI*, and the fragments were analyzed by standard methods involving agarose gel electrophoresis, transfer to nitrocellulose filters, and hybridization with radioactive EBV DNA or complementary RNA. Sequence variability among different EBV DNA isolates was largely confined to the A, C, and I fragments. These results are discussed in relation to the linkage map of the *EcoRI* fragments of EBV DNA. The *EcoRI* cleavage pattern of intracellular viral DNA of an EBV-like virus from baboon cells, *Herpesvirus papio*, was entirely different from that of human EBV isolates. The results show that, at the present level of resolution, no obvious disease-related differences could be discerned among EBV DNA isolates of tumor or nontumor origin. However, more subtle sequence differences within the EBV genome may still be of critical biological importance. (27 refs)

- 79-5781 Relationship Between Epstein-Barr Virus Genome Number, Amount of Nuclear Antigen, and Early Antigen Inducibility in Diploid and Tetraploid Lymphoma Cells of Related Origin. (Eng) Shapiro, I. M. (Dept. Tumor Biology, Karolinska Institutet, S-104 01 Stockholm 60, Sweden); Luka, J.; Andersson-Anvret, M.; Klein, G. *Intervirology* 12(1): 19-25; 1979.

Among several near-diploid and near-tetraploid Raji sublines and somatic Raji/Raji hybrids, a linear relationship was found between the number of Epstein-Barr virus (EBV) genome copies and the relative amount of EBV-determined nuclear antigen per cell. Inducibility of the viral cycle by iododeoxyuridine and by P3HR-1 virus superinfection may be related to the number of resident EBV genome copies per haploid target cell. It is suggested that cells with ≤ 25 EBV genome equivalents per diploid chromosome set will have a very low inducibility. An increased number of EBV genome copies may increase the chances for initiation of the viral cycle. Alternatively, the number of EBV genome copies and inducibility may be regulated by coordinated controls. (15 refs)

- 79-5782 Mode of Integration of Epstein-Barr Virus Genome into Host DNA in Burkitt Lymphoma Cells. (Eng) Kolias, S. I. (Theagenion Medical Inst., Thessaloniki, Greece). *J Gen Virol* 44(2): 573-576; 1979.

The integrated Epstein-Barr virus (EBV) DNA found in Burkitt lymphoma (BL) cells was studied. DNA was fractionated by cesium chloride (CsCl) density gradient centrifugation and characterized by hybridization with EBV complementary RNA (cRNA). In neutral CsCl gradients, high mol wt DNA from an African BL biopsy showed a reduction in size which caused a shift of the EBV sequences to higher densities. In the case of high-mol-wt DNA from the SU-AmB-2 BL cell line, a similar reduction in size of the DNA had no apparent effect on the density of DNA. These results show that in the case of the African BL, EBV DNA sequences integrated into the host genome are very large, whereas EBV DNA integrated into SU-AmB-2 cells is very small. It is concluded that few sites of integration exist in the cells of the African BL biopsy, whereas cells of the American SU-AmB-2 line contain a larger number of integration sites. (10 refs)

- 79-5783 Growth of Diploid, Epstein-Barr Virus-carrying Human Lymphoblastoid Cell Lines Heterotrans-

planted into Nude Mice under Immunologically Privileged Conditions. (Eng) Giovanella, B. (Cancer Res. Lab., St. Joseph Hosp., Houston, TX 77002); Nilsson, K.; Zech, L.; Yim, O.; Klein, G.; Stehlin, J. S. *Int J Cancer* 24(1): 103-113; 1979.

Eighteen diploid Epstein-Barr virus-carrying human lymphoblastoid cell lines (LCL) of presumed nonneoplastic origin were inoculated intracerebrally into nude mice. All 18 lines grew, killing their hosts within 7-25 days except for 2 that grew more slowly. At autopsy, the brains of these mice were found to be invaded by infiltrating lymphomas. Sixteen of the lymphomas, when recultured in vitro, gave rise to cell lines with growth properties and a morphology indistinguishable from those of the inoculated LCL. Chromosome examinations of seven cell lines that grew as lymphomas in the brain showed that three were still normal diploid on reimplantation, whereas the remaining four had become aneuploid. When four lines derived from the intracerebral lymphomas (2 diploid, 1 aneuploid, and 1 untested) were injected sc into adult nude mice, sc into newborn nude mice, or intracerebrally into adult normal mice, none of them grew. However, they grew rapidly when they were injected sc into newborn nude mice. One of these lines, U-1450, was injected sc into adult nude mice treated with antilymphocyte serum. Small nodules developed at the inoculation site. A cell line (1450 ALSAD) was cultured from one nodule. It was morphologically indistinguishable from the line of origin. The lines obtained from nude mice inoculated with polyclonal LCL seemed to have a restricted clonal representation, but they were not monoclonal, as evidenced by analyses of their immunoglobulin synthesis pattern. (40 refs)

- 79-5784 In Vitro Transforming Activity of Epstein-Barr Virus (EBV). II. Differences Between M81 and B95-8 EBV Strains. (Eng) Desgranges, C. (150 Cours Albert Thomas, 69372 Lyon, France); Lavoue, M. F.; Patet, J.; de-The, G. *Biomedicine* 30(2): 102-108; 1979.

Lymphocytes from 38 human cord blood and 9 adult circulating blood samples were infected in parallel either with the B95-8 Epstein-Barr virus (EBV) strain (produced by cotton-top marmoset lymphocytes transformed by EBV originating from an infectious mononucleosis line) or with the M81 EBV strain (produced by *Callithrix jacchus* marmoset lymphocytes transformed by EBV originating from a nasopharyngeal carcinoma derived line). Significant differences observed in the lymphoblastoid lines obtained involved cell morphology, cell growth and synthesis of viral antigen. Cord blood lymphocytes infected with M81 virus resulted in lymphoblastoid lines where early antigen and viral capsid antigen synthesis and production of virions took place, whereas this was not observed in B95-8-induced lines. - 79-5785 Antigenic Relationships Between Polypeptides Derived from Plantar and Hand Wart Viruses. (Eng) Staquet, M. J. (F.R.A. INSERM No. 11, Recherche Dermatologique et Immunologie, Clinique Dermatologique, Hopital Ed. Herriot, 69374 Lyon Cedex 2, France); Viac, J.; Thivolet, J. *J Gen Virol* 43(3): 713-717; 1979.

A comparative study was made of the antigenicity and immunogenicity of various polypeptides derived from plantar and hand wart viruses. Guinea pigs immunized with polypeptides derived from plantar and hand wart viruses (PV and HV) developed both humoral and cell-mediated immunity. The specificity of the antiserum was determined by indirect im-

muno fluorescence (IF) tests, and cellular immunity was determined by id tests. Although whole PV and HV particles appeared to be immunologically analogous, they had different polypeptide patterns, as shown by analysis on acrylamide slab gels. In particular, the P2 polypeptide (major virus protein) of PV had a different mol wt (56,750) than that of HV (54,500), and it induced high antibody titers in the animals. In addition, the immune sera specifically labeled wart substrates, as shown in the IF test, demonstrating that no cross humoral reaction occurs between these two polypeptides. Furthermore, a delayed hypersensitivity reaction was observed in P2 polypeptide-inoculated guinea pigs when whole particles were introduced in skin tests, but a cross-reactivity between PV and HV was noticed at the cellular level. Virus particles isolated from the lesions of a patient bearing extensive common hand warts possessed all the biochemical and immunological characteristics of PV, particularly with regard to the P2 polypeptide. Such a case may represent plantarlike warts located on the hands. (18 refs)

- 79-5786 Sequence from Early Region of Polyoma Virus DNA Containing Viral Replication Origin and Encoding Small, Middle and (Part of) Large T Antigens. (Eng) Soeda, E. (Nat'l. Inst. Genetics, Misima 411, Japan); Arrand, J. R.; Smolar, N.; Griffin, B. E. *Cell* 17(2): 357-370; 1979.

The sequence of about one-third of the polyoma virus (PV) genome is presented. This sequence covers the origin of replication of two large plaque strains (A2 and A3) of PV. The two strains differ by 11 base pairs in the origin region. A model for replication is suggested. The sequence probably also covers the entire coding region of two PV early proteins, small and middle tumor (T) antigens, as well as part of the coding region for large T antigen. Over a small region of the DNA, all three coding frames contain termination codons, which suggests a need for spliced early messenger RNA's. In another region of the DNA, two coding frames can be used. Correlation with protein data suggests that one frame codes for part of middle T antigen and the other for part of large T antigen. (47 refs)

- 79-5787 Role of Interferon in the Pathogenesis of Virus Diseases in Mice as Demonstrated by the use of Anti-Interferon Serum. VI. Polyoma Virus Infection. (Eng) Gresser, I. (Institut de Recherches Scientifiques sur le Cancer, Villejuif, France); Maury, C.; Kress, C.; Blangy, D.; Maunoury, M. T. *Int J Cancer* 24(2): 178-183; 1979.

The effect of a single ip injection of potent sheep anti-mouse interferon globulin (SAIG, 50-100 μ l) on polyoma-virus (PV)-induced early runting disease and tumor formation was studied using Swiss mice. Mice treated with PV (50 μ l ip immediately before SAIG during the first 24 hr of life) grew as well as mice treated with PV + SAIG for the first 11 days, after which 10%-20% of the PV-treated mice and most of the PV + SAIG-treated mice were runted. Mortality during the first 2 mo was 0%-25% for the PV-treated mice and 70%-100% for the PV + SAIG-treated mice. Deaths usually occurred during the third or fourth week. Histologic examination showed no differences between mice treated with PV and those treated with PV + SAIG. The median tumor-inducing doses for the PV- and PV + SAIG-treated mice were 10^6 and 10^2 - 10^3 plaque-forming units, respectively. The tumor incidence was greater and the tumor latent period reduced in mice treated with PV + SAIG compared with those given PV alone. The sites of tumor development were similar in the two groups. The titers of virus in the thymuses and spleens of the PV

+ SAIG-treated mice were greater than those in the PV-treated mice. No interferon was demonstrated in the PV-treated mice, whether or not they were given SAIG. The results suggest that interferon is an important factor in determining the susceptibility of newborn mice to PV. (33 refs)

- 79-5788 The Colinear Alignment of the Genomes of Papovaviruses JC, BK, and SV40. (Eng) Law, M. F. (Lab. Pathology, NCI, Bethesda, MD 20205); Martin, J. D.; Takemoto, K. K.; Howley, P. M. *Virology* 96(2): 576-587; 1979.

The polynucleotide sequence homology among the DNA's of polyomaviruses JC, BK, and simian virus 40 (SV40) were analyzed under a range of nonstringent hybridization conditions. When the hybridizations were performed at $T_m - 36^\circ\text{C}$, conditions that would detect regions of homology with as much as 26% base mismatch, extensive homology was detected in all gene regions between the JC genome and both the BK and SV40 DNA's. The regions of strongest sequence homology between the genomes formed stable duplexes at $T_m - 21^\circ\text{C}$, indicating at least an 85% base match. By two-dimensional cross-hybridization of restriction endonuclease cleavage fragments of JC to both those of BK and SV40 under nonstringent conditions, it was possible to map the homologous DNA fragments of each pair of viruses with respect to each other. The physical maps of these polyomaviruses could be colinearly aligned using the conserved single *EcoRI* site in each genome as the 0 map position. The region of strongest homology among these three genomes was localized in a narrow segment (0.76 to 0.85 map unit) in the late region, which in the SV40 genome contains the codons for the N-terminal half of the minor viral protein VP2. (52 refs)

- 79-5789 The Spliced Structure of BK Virus mRNAs in Lytically Infected and Transformed Cells. (Eng) Manaker, R. A. (Lab. Molecular Virology, NCI, NIH, Bethesda, MD 20014); Khoury, G.; Lai, C. J. *Virology* 97(1): 112-121; 1979.

The messenger RNA (mRNA) molecules of human papovavirus BK virus (BKV) in lytically infected cells and in a transformed human cell culture cloned from a population infected with UV-inactivated BKV were mapped by the nuclease S1 technique. Two BKV mRNA species were synthesized in cells early after lytic infection and in virus-transformed cells. The 5' end of one RNA species (and of the other by inference) mapped at approx 0.66 map unit near the origin for DNA replication, and the 3' ends of both molecules mapped at 0.16 unit. The intervening sequences deleted from these mRNA's were located between 0.585 and 0.53 map unit for one species and between 0.535 and 0.53 map unit for the other. The map positions of these RNA's were similar to the locations of the SV40 mRNA's that encode the large tumor (T) antigen and small t antigens, respectively. The genomic locations of the late BKV mRNA species were also determined. The body sequences of the late 16S RNA mapped between 0.765 and 0.16 unit, and those of the late 19S RNA mapped between 0.765 and 0.16 unit. A significant proportion of these late transcripts contained a leader RNA transcribed from 0.70 to 0.76 map unit. The spliced late lytic BKV RNA's synthesized in both human embryonic kidney cells and African green monkey kidney cells appeared to be identical. (38 refs)

- 79-5790 Tumorigenicity and Karyotype of Rat Embryo Cell Lines Transformed by BK Virus. (Eng) Karjalainen,

H. E. (Dept. Clinical Microbiology, Univ. Kuopio, POB 138, 70101 Kuopio 10, Finland); Salmi, A.; Mantylarvi, R. A. *Acta Pathol Microbiol Scand [A]* 87(4): 245-253; 1979.

The karyotype and tumorigenicity of several rat embryo cell lines transformed by BK virus were compared. A rat embryo cell line transformed by BK virus was used to induce tumors in rats, and cell lines were established from these tumors. Other sublines were obtained by in vitro cloning of the parental line. The in vitro-cloned sublines had a low tumorigenicity. The tumorigenicity of the in vivo-selected tumor cell lines varied from high to undetectable. The tumor cell line with the highest tumorigenicity also had the highest saturation density in vitro, but otherwise there was little correlation between tumorigenicity and the in vitro characteristics of the cells. Karyotype analysis was done for two cell lines with high and low tumorigenicity, respectively, and with a near-diploid complement of chromosomes. The findings agreed with the expression-suppression model of Rabinowitz and Sachs, according to which the tumorigenicity of a cell line would depend on the balance between expression and suppression chromosomes. The suppression chromosomes seemed to be confined to Group A, the expression chromosomes to Group B. (39 refs)

- 79-5791 Polyoncogenicity and Insulinoma-inducing Ability of BK Virus, a Human Papovavirus, in Syrian Golden Hamsters. (Eng) Uchida, S. (Dept. Viral Infection, Inst. Medical Science, Univ. Tokyo, Tokyo 108, Japan); Watanabe, S.; Aizawa, T.; Furuno, A.; Muto, T. *J Natl Cancer Inst* 63(1): 119-126; 1979.

The oncogenic potential of the human papovavirus BK virus (BKV) was studied in Syrian golden hamsters. Newborn hamsters were inoculated intracerebrally with a series of purified and concentrated BKV samples from a single stock of Gardner's original strain. Most (60%-100%) of the hamsters developed various tumors 3-9 mo later. The most common of tumors were ventricular tumors (choroid plexus papillomas and ependymomas, 7%-53%), malignant insulinomas (0%-92%), and osteosarcomas (0%-50%). Fifty-nine of the 60 tumors tested were positive for tumor antigen, but virus was rescued by the cell fusion method from only 1/11 cell lines derived from these tumors. The incidence of insulinomas varied greatly with the virus sample; the two samples that showed the highest incidences (47% and 92%) originated from one parental virus stock, and samples with lower incidences (0%-9%) originated from another parental stock. These results suggest the presence of a BKV mutant(s) differing in capacity to induce insulinomas. A functional insulinoma cell line was established by injecting a minced BKV-induced insulinoma into weanling hamsters. (31 refs)

- 79-5792 Altered Nuclear Structure during Productive and Abortive Infections with SV40 DNA. (Eng) Robb, J. A. (Dept. Pathology, Green Hosp. Scripps Clinic, La Jolla, CA 92037); Rowley, R. D. *Intervirology* 12(1): 57-64; 1979.

Alterations in the nuclear morphology of five mammalian cell types following infection with simian virus 40 (SV40) DNA was studied using SV40 large-T antigen-specific immunofluorescence. A striking alteration in nuclear morphology occurred in cells infected by form I SV40 DNA (virion DNA with the virion proteins removed) but not in those infected by SV40 virions. Infection by SV40 virions was far more efficient than that by form I DNA, however. It was unlikely that SV40 or cellular DNA synthesis had any role in the genesis of the observed nuclear abnormalities; cells

with preexisting abnormal morphologies were not being selectively infected by the SV40 DNA. The finding that the formation of binucleate and fragmented nuclei following SV40 DNA infection was dependent on the cell type infected suggests that a cellular function(s) was involved in the nuclear alteration. (18 refs)

- 79-5793 Segments of Simian Virus 40 DNA Spanning Most of the Leader Sequence of the Major Late Viral Messenger RNA Are Dispensable. (Eng) Subramanian, K. N. (Dept. Microbiology, Univ. Illinois at Medical Center, Chicago, IL 60612). *Proc Natl Acad Sci USA* 76(6): 2556-2560; 1979.

The construction, by a restriction-ligation procedure, isolation, and DNA sequence of viable deletion mutants of simian virus 40 (SV40) spanning the leader sequence of the 16S messenger RNA (mRNA) are described. With the construction procedure used, the size and location of the deletions could be predetermined in vitro. The DNA products were subjected to agarose gel electrophoresis before and after ligation, to ensure that the background due to wild-type plaques is <10% of the total numbers. The deletions ranged from 20 to 223 nucleotides. All these deletion mutants were viable and grew without helper virus. The largest deletion removed the entire leader sequence except for six nucleotides at the 3' end that are probably involved in covalent linkage with the 5' end of the body of the mRNA located 937 nucleotides away. Three of the deletion mutants removed the 5' end of the leader that normally contains the cap structure of the mRNA. A large segment immediately preceding the leader sequence was also removed in one of these mutants, ruling out generation of the 5' end of the mRNA via initiation of transcription at this point. The circularization of linear infecting DNA producing the DNA of the deletion mutants proceeded mainly by way of blunt end ligation in vivo. (29 refs)

- 79-5794 Transcription of Nucleosomal DNA in SV40 Minichromosomes by Eukaryotic and Prokaryotic RNA Polymerases. (Eng) Meneguzzi, G. (Centre de Biochimie, Faculté des Sciences, 06034 Nice, France); Chenciner, N.; Milanese, G. *Nucleic Acids Res* 6(8): 2947-2960; 1979.

Simian virus 40 (SV40) minichromosomes extracted from virions were transcribed with eukaryotic RNA polymerase B and with *Escherichia coli* RNA polymerase. With both RNA polymerases, transcription of minichromosomes was approx 25%-30% that of 'naked' SV40 superhelical DNA after 30 min of synthesis. Thus, for both eukaryotic and prokaryotic enzymes the presence of nucleosomes on the viral DNA did not completely inhibit transcription. Sedimentation analysis demonstrated that the size of RNA made on minichromosomes by either polymerase was smaller than the corresponding RNA made on deproteinized superhelical DNA. The av size reduction was from 1,500 to 1,000 nucleotides with *E. coli* polymerase and from approx 1,200 to 900 nucleotides with calf thymus RNA polymerase B. It is suggested that both RNA polymerases can transcribe portions of minichromosomal DNA that include a few nucleosomes. It is shown that minichromosome structure is not substantially altered by transcription by using (³H-thymidine)-labeled SV40 minichromosomes which were transcribed with *E. coli* RNA polymerase into ³²P-labeled RNA. Nascent RNA chains were only found associated with minichromosomes that had a full complement of nucleosomes. When tritium-labeled 'naked' SV40 superhelical DNA was used as the template, it was shown that RNA chains on the complex were precursors to those found in the major, slow sedimenting RNA peak. When SV40 minichromosomes or an

equivalent amount of deproteinized superhelical SV40 DNA was transcribed in vitro with *E. coli* or calf thymus B RNA polymerases, it was shown that with *E. coli* RNA polymerase, the fraction of RNA which became RNase resistant after self-hybridization was over 30% in the case of minichromosomes, as compared with 15% when 'naked' DNA was transcribed. Thus, a marked reduction in strand selectivity is imposed by nucleosomes on transcription with the prokaryotic enzyme. The poor strand selectivity exhibited by the eukaryotic enzyme was not improved when minichromosomes were used as template instead of 'naked' DNA. (30 refs)

- 79-5795 Sequence Heterogeneity at the 5' Termini of Late Simian Virus 40 19S and 16S mRNAs. (Eng) Canaani, D. (Dept. Virology, Weizmann Inst. Science, Rehovot, Israel); Kahana, C.; Mukamel, A.; Groner, Y. *Proc Natl Acad Sci USA* 76(7): 3078-3082; 1979.

In an attempt to identify the promoter for simian virus 40 (SV40) late transcription, the 5'-capped oligonucleotides of SV40 late 19S and 16S messenger RNA's (mRNA's) were examined. The 5'-capped leader sequence of the most abundant 19S and 16S mRNA's was previously mapped between 0.67 and 0.76 map units. In these studies, the two late mRNA species were found to contain multiple 5' ends. Eight different RNase T2-resistant cap structures were identified: m⁷GpppmAmpU (47%); m⁷GpppmAmpUmpU (19%); m⁷GpppmAmpC (16%); m⁷GpppmAmpCmpA (5%); m⁷GpppmAmpG (6%); m⁷GpppGmpC (3%); m⁷GpppmAmp-GmpA (2%); m⁷GpppGmpCmpG (2%). Capped T1 oligonucleotides of 19S and 16S mRNA's were isolated by two different procedures: (1) chromatography on a diethylaminoethylcellulose column followed by paper electrophoresis and (2) two-dimensional electrophoresis/homochromatography. Cap structures of the isolated 5' oligonucleotides were identified. Each of the major caps was found to be associated with a few different 5' oligonucleotides, implying a vast heterogeneity at the termini of SV40 late mRNA's. The results suggest that on SV40 DNA, RNA polymerase II has a repertoire of initiation points. In most of the cases, initiation takes place with ATP followed by a pyrimidine. Alternatively, transcription may start at one specific point, but a unique mechanism of processing generates heterogeneous populations of termini with a common 5'-ATP. (41 refs)

- 79-5796 Identification and Mapping of N⁶-Methyladenosine-containing Sequences in Simian Virus 40 RNA. (Eng) Canaani, D. (Dept. Virology, Weizmann Inst. Science, Rehovot, Israel); Kahana, C.; Lavi, S.; Groner, Y. *Nucleic Acids Res* 6(8): 2879-2899; 1979.

To learn more about the functional role of internal methylated residues, sequences containing N⁶-methyladenosine (m⁶A) were identified and compared in simian Virus 40 (SV40) nuclear and messenger RNA (nRNA and mRNA) and in host cellular mRNA. The av number of M⁶A oligonucleotides in SV40 16S and 19S mRNA's was determined, and the methylated sequences were localized on the viral genome. Late SV40 16S and 19S mRNA's contained an av of three MA residues/mRNA molecule. In both viral and cellular mRNA's, the methylated residues occurred in either Gpm⁶ApC or (Ap)m⁶ApC RNA sequences, where n = 1-4. More than 60% of the m⁶A residues in SV40 16S and 19S mRNA's were in Gpm⁶ApC sequences, despite there being twice as many (A)nAC than GAC sequences in these mRNA's. In the 16S

mRNA, two of the m⁶A residues were at the 5' coding region between 0.95 and 0.0 map units; the third residue mapped between 0.0 and 0.14 map units in the translated portion of the mRNA. The methylation pattern of the 19S mRNA was similar, although some differences between the 16S and 19S mRNA's were observed in the content and localization of the longer (AP)/m⁶ApC sequences. These results provide the first example of the precise localization of internal methylation sequences in mRNA species with defined coding specificity. The results imply that (1) localization of m⁶A residues is not random but rather specific to a particular region of the RNA; (2) apart from sequence specificity, other structural features of the mRNA may influence internal methylation, and (3) m⁶A residues are present in coding regions of SV40 mRNA's. (39 refs)

- 79-5797 Survival of Apurinic SV40 DNA in the D-complementation Group of Xeroderma Pigmentosum. (Eng) Kudrna, R. D. (Dept. of Biochemistry, Univ. California, Berkeley, CA 94720); Smith, J.; Linn, S.; Penhoet, E. E. *Mutat Res* 62(1): 173-181; 1979.

The survival of depurinated form I simian virus 40 (SV40) DNA was measured in normal human fibroblasts and in D-complementation xeroderma pigmentosum (XP) fibroblasts by an infective center assay. Heat-acid treatment and methyl methanesulfonate (MMS) were used as depurinating agents. After 3 hr of depurination by heat-acid treatment, infectivity in normal cells was <15% of the control levels, compared with >50% for the XP cells. Similar results were obtained with MMS-treated DNA. These results are contrary to expectation, since apurinic endonuclease activity, which is presumed to be involved in the repair of apurinic sites, is much lower in XP D-cell strains than in normal cell strains. The results indicate that there may be another mechanism for the repair of apurinic sites. (34 refs)

- 79-5798 Relationship Between Single-stranded DNA Isolated from Mouse Cells Transformed by Simian Virus 40 and Transcription of Cellular and Virus Genes. (Eng) Shaoof, D. (Laboratoire de Biologie Moléculaire, Groupe de Recherche No. 8, C.N.R.S., Institut Gustave-Roussy, 94800 Villejuif, France); Hanania, N.; Harel, J.; May, E. *J Gen Virol* 43(3): 571-581; 1979.

The relationship between single-stranded DNA (ssDNA) isolated from SV-3T3 mouse cells nonproductively transformed by simian virus 40 (SV40) and transcription of cellular and viral genes was investigated. A minor fraction of ssDNA was isolated by an improved method of hydroxyapatite chromatography (HAC) from the native nuclear DNA (nDNA) of SV-3T3 cells. Molecular hybridization, monitored by the use of S₁ nuclease, HAC, isopycnic centrifugation, and thermal melting, showed that ssDNA from SV-3T3 cells (which amounts to 1.5%-2% of the total nDNA) has the same characteristics as ssDNA previously isolated from other cell species. Only 27%-28% of the SV-3T3 ssDNA reassociated with itself, but the majority reassociated with the nonrepetitive portion of nDNA and up to 38% hybridized to homologous RNA. Only 7%-8% of bulk nDNA hybridized to homologous RNA. Highly radioactive virus probes (SV40-³H-complementary RNA synthesized in a cell-free system and the separated early and late strands of SV40 DNA labeled with ³²P) were annealed to different excess amounts of cellular DNA. Each probe hybridized at saturation levels, and the various reaction kinetics indicated that ssDNA is greatly enriched in virus sequences, mainly those originating from the early DNA strand, which is predominantly expressed in SV-3T3 cells. (27 refs)

- 79-5799 Persistence of Phage λ DNA in Genomes of Mouse Cells Transformed by λ-carrying SV40 Vectors. (Eng) Muzyczka, N. (Dept. Immunology and Medical Microbiology, Univ. Florida, Gainesville, FL 32610). *Gene* 6(2): 107-122; 1979.

Experiments aimed at establishing methods for incorporating foreign DNA into the chromosomal DNA of mammalian cells are described. To test the suitability of simian virus 40 (SV40) DNA as a vector for inserting DNA segments into the chromosomes of mammalian cells, an *Eco*RI-A fragment of bacteriophage λ DNA was covalently joined to a fragment of SV40 DNA and used to transform BALB/c 3T3 mouse cells in culture. Three independent, morphologically transformed clones were obtained that were positive for SV40 tumor (T) antigen by immunofluorescence staining. DNA from each transformant was examined by restriction enzyme analysis and found to contain both λ and SV40 sequences. Comigration of some fragments containing λ and SV40 sequences following digestion of transformed cell DNA by each of four different restriction enzymes indicated that part of the retained λ and SV40 DNA was linked in two of the three lines. In the third line, however, none of the restriction fragments had both λ and SV40 sequences. Although the presence of nonintegrated λ DNA was not excluded, at least some of the λ DNA appeared to be linked to host cell DNA. The results of digestion by *Eco*RI suggested that in some cases, the transforming linear molecule had probably circularized prior to integration. (37 refs)

- 79-5800 Simian Virus 40 Recombinants Are Produced at High Frequency During Infection with Genetically Mixed Oligomeric DNA. (Eng) Wake, C. T. (Marrs McLean Dept. Biochemistry, Baylor Coll. Medicine, Houston, TX 77030); Wilson, J. H. *Proc Natl Acad Sci USA* 76(6): 2876-2880; 1979.

A strategy for increasing simian virus 40 (SV40) recombination by bypassing the inefficient intermolecular step is described. Oligomeric SV40 was constructed in vitro by ligation of mixtures of pairs of linear DNA's carrying genetically distinct temperature-sensitive (ts) mutations. Cultured monkey cells infected with the unfractionated ligation products yielded frequencies of nonparental recombinant progeny that were increased up to 500-fold relative to cells infected with a mixture of the untreated circular molecules. Pairwise crosses were performed with tsB4, tsB8, and tsBC11 DNA's, using unfractionated oligomers constructed from linear molecules cleaved by *Eco*RI or *Bam*HI. In each cross, the fraction of progeny with nonparental genotypes was roughly proportional to the physical distances between the mutant sites. These results suggest a random, rather than site-specific, conversion of oligomers to monomers. Somewhat surprisingly, nonligated mixtures of linear tsB4 and tsB8 DNA's, created by *Eco*RI digestion, produced a 40- to 100-fold increase in the frequency of nonparental progeny. These results indicate that intermolecular associations must occur with fairly high efficiency between these linear molecules. (26 refs)

- 79-5801 Protein Kinase Activity Associated with Simian Virus 40 T Antigen. (Eng) Griffin, J. D. (Sidney Farber Cancer Inst., Boston, MA 02115); Spangler, G.; Livingston, D. M. *Proc Natl Acad Sci USA* 76(6): 2610-2614; 1979.

The results of experiments designed to assess whether any of the simian virus 40 (SV40) tumor (T) antigens have protein kinase activity are reported. Incubation of SV40 (T) antigen-containing immunoprecipitates with [γ -³²P]ATP resulted in the incorporation of

radioactive phosphate into large T antigen. Highly purified preparations of large T antigen from a SV40-transformed cell line, SV80, were able to catalyze the phosphorylation of a known phosphate acceptor, casein. The kinase activity migrated with large T antigen through multiple purification steps. Sedimentation analysis under non-T-antigen-aggregating conditions revealed that kinase activity and the immunoreactive protein comigrated as a 6S structure. The kinase activity of purified preparations of large T antigen could be specifically adsorbed to solid-phase anti-T IgG, and partially purified T antigen from a SV40 temperature-sensitive tsA transformant was thermolabile in its ability to phosphorylate casein when it was compared with comparably purified wild-type T antigen. These observations indicate that SV40 large T antigen is closely associated with protein kinase (ATP:protein phosphotransferase) activity. (47 refs)

- 79-5802 Intracellular Forms of Simian Virus 40 Nucleoprotein Complexes. II. Biochemical and Electron Microscopic Analysis of Simian Virus 40 Virion Assembly. (Eng) Coca-Prados, M. (Rockefeller Univ., New York, NY 10021); Hsu, M. T. *J Virol* 31(1): 199-208; 1979.

The simian virus 40 virion assembly process was studied with pulse-labeling kinetics of virion proteins, CsCl gradient analysis, electron microscopy, and low-salt gel electrophoresis. The results obtained are consistent with the model of gradual addition and organization of capsid proteins around simian virus 40 chromatin. Empty virions, as previously observed in the CsCl gradient, were found to be the dissociation product of immature virus. Histone H1 was found in simian virus 40 chromatin and virion assembly intermediates but not in the mature virion banding at 1.34 g/ml in the CsCl gradient. (21 refs)

- 79-5803 Biology of Simian Virus 40 (SV40) Transplantation Antigen (TrAg). V. In Vitro Demonstration of SV40 TrAg in SV40 Infected Nonpermissive Mouse Cells by the Lymphocyte Mediated Cytotoxicity Assay. (Eng) Pretell, J. (Dept. Pathology, Yale Univ. Coll. Medicine, New Haven, CT 06520); Greenfield, R. S.; Tevethia, S. S. *Virology* 97(1): 32-41; 1979.

The development of simian virus 40 (SV40)-specific transplantation antigen (TrAg) on the surface of nonpermissive mouse cells infected with SV40 was demonstrated in vitro using a sensitive, lymphocyte-mediated, ⁵¹Cr-release cytotoxicity assay. The assay was specific for the detection of SV40 TrAg. The antigen was detected 24 hr after infection of mouse cells with SV40, and high levels of TrAg expression persisted for as long as 96-120 hr after virus infection. The development of TrAg on the surface of the infected cells correlated with the synthesis of tumor antigen in nucleus. The synthesis and expression of TrAg on the surface of these cells may be an important step in the development of cell-mediated type immunological resistance in an SV40-inoculated host, leading to the elimination of stably transformed cells. (27 refs)

- 79-5804 Concanavalin A-mediated In Vitro Activation of Lymphocytes Primed Against Syngeneic SV40-induced Tumor-associated Antigens in Mice into Secondary Effector Cells Capable of Specifically Preventing Tumor Growth. (Eng) Glaser, M. (Dept. Biochemistry, George Washington Univ. Medical Center, 2300 I St., N.W., Washington, DC 20037). *Cell Immunol* 46(1): 201-207; 1979.

Spleen cells from female BALB/c mice immunized against a syngeneic simian virus 40 (SV40)-induced tumor, mKSA, prevented specifically the growth of the corresponding tumor in a tumor cell neutralization assay following preincubation of the cells for 5 days with mitogenic concentrations of concanavalin A (Con A). This reactivity was T-cell-dependent, independent of remaining Con A, and was detected at least up to 60 days following in vivo antigenic immunization. A similar reactivity was obtained with mitogenic concentrations of phytohemagglutinin but not with the B-cell mitogen lipopolysaccharide. Since this reactivity was indistinguishable from that obtained upon in vitro secondary antigenic stimulation with SV40-transformed cells, it is suggested that activation of precytotoxic cells against a syngeneic tumor by Con A into cytotoxic cells may be mediated by the same or similar receptors triggered by the stimulating tumor-associated antigens. (17 refs)

- 79-5805 Lysosome Stability during Lytic Infection by Simian Virus 40. (Eng) Einck, K. H. (Dept. Microbiology, Univ. Massachusetts, Amherst, MA 01003); Norkin, L.C. *Intervirology* 12(1): 47-56; 1979.

CV-1, LLC-MK₂, and BALB 3T3 cells infected with simian virus 40 (SV40) were studied to determine whether their lysosomes ruptured prior to cell death. As indicated by trypan blue staining, 40% to 80% of the CV-1 cells had undergone irreversible injury by 48 hr postinfection. However, as indicated by staining with acridine orange or neutral red, the lysosomes were intact at 24 and 48 hr postinfection. In some of the infected cells, the neutral red-stained lysosomes appeared to be grossly swollen. All of the cells containing such lysosomes were able to exclude trypan blue. Acid phosphatase activity was localized in discrete cytoplasmic particles at 48 hr, as indicated by histochemical staining of both fixed and unfixed cells. The results suggest that impaired membrane metabolism plays an important role in cell killing by SV40. (21 refs)

- 79-5806 SV40-related T-Antigen Expression in Human Meningiomas with Normal and G-22-monosomic Karyotype. (Eng) May, G. (Institut für Humangenetik, Universität des Saarlandes, 6650 Hamburg, W. Germany); Fischer, H.; Zang, K. D. *J Gen Virol* 43(3): 697-700; 1979.

Meningioma cell cultures were analyzed for the presence of nuclear fluorescence specific to simian virus 40 (SV40) tumor (T) antigen by the indirect immunofluorescence technique. Six of 16 meningiomas tested in early subculture showed SV40 T antigen. Two different antisera specific for T antigen were used: one gave a positive reaction with six tumors, and the other gave a positive reaction with only two tumors. In one T-antigen-positive meningioma, the typical nuclear fluorescence changed, beginning with the second subculture, into an unusual brilliant granular pattern that was irregularly distributed over the nuclei. In six meningiomas, a specific chromosome aberration (monosomy G 22) was established. However, up to now, no clear correlation between karyotype and T-antigen expression could be found: cells from three meningiomas with positive reactions had normal karyotypes, whereas those from three tumors with monosomy G 22 showed no T antigen. (8 refs)

- 79-5807 Vp1 Affects Intracellular Localization of Vp3 Polypeptide During Simian Virus 40 Infection. (Eng)

Kasamatsu, H. (Dept. Biology, Univ. California at Los Angeles, 405 Hilgard Ave., Los Angeles, CA 90024); Nehorayan, A. *Proc Natl Acad Sci USA* 76(6): 2808-2812; 1979.

To understand the functions of simian virus 40 (SV40) genes, the effect of temperature-sensitive (ts) mutations on the localization of viral antigens after infection was studied. Permissive cells (TC7) were infected with SV40 mutants ts in the complementation groups A, B, C, BC, and D at permissive and nonpermissive temperatures. Cells were examined for the localization of viral polypeptide antigens by immunofluorescent staining with monospecific antibodies. (1) The appearance of Vp1 antigen in cells infected by tsB, C, or BC mutants was not affected appreciably by the mutations. (2) The appearance of Vp3 antigen was affected by mutations in B, C, or BC. Vp3 antigen is confined to the nuclei in cells infected by wild-type virus. With mutant virus infection, Vp3 antigen is found in the cytoplasm, perinuclear region, and nucleoli. (3) The tsD mutants and the tsA mutants did not express either Vp1 or Vp3 antigens at the nonpermissive temperature. (4) Nucleoli seem to play an essential role in the biosynthesis and assembly of viral polypeptides. Thus, mutations in any one of complementation groups B, C, or BC, which are within the structural gene for Vp1, alter the intracellular distribution of another late gene product, Vp3. These results suggest that the amino acid sequences of Vp1 polypeptide play a role(s) in the transport of viral antigens across internal membranes and/or in virus assembly. (29 refs)

79-5808 Studies on Tumor-associated Antigens of Sarcoma Induced by Calf Adenovirus Type 3 and by Human Adenovirus Type 12 in Hamsters. (Bul) Bashkaev, I. S. (P.A. Gertsen Moscow Scientific Res. Inst. Oncology, Moscow, USSR); Ageenko, A. I.; Silianovska, K.; Boeva, M. *Onkologiya* 16(1): 32-34; 1979.

The tumor-associated antigens of sarcomas induced by calf adenovirus type 3 (sarcoma A-3) and human adenovirus type 12 (sarcoma A-12) in hamsters were studied by gel immunodiffusion. Complete serological identity of the two sarcomas was determined. The antigens contained by the two tumors were very similar, which was demonstrated by the fact that their precipitation lines coincided. In both cases, these antigens were present in the tumors only. The findings indicate the similarity of the two adenoviruses. (9 refs)

79-5809 Mutations that Allow Human Ad2 and Ad5 to Express Late Genes in Monkey Cells Map in the Viral Gene Encoding the 72K DNA Binding Protein. (Eng) Klessig, D. F. (Cold Spring Harbor Lab., P.O. Box 100, Cold Spring Harbor, NY 11724); Grodzicker, T. *Cell* 17(4): 957-966; 1979.

The isolation of five independent host-range mutants (Ad2hr400-hr403, Ad5hr404) of human adenovirus serotype 2 and 5 (Ad2 and Ad5) that overcome the block to growth of wild-type adenovirus in monkey cells and form plaques and multiply efficiently in monkey and human cells is reported. The alteration in each of these mutants allowed the full expression of all viral late genes, in marked contrast to the depressed synthesis of many late proteins in monkey cells infected with the parental Ad2 or Ad5. The altered gene encoded a diffusible product, since the mutation acted in trans to enhance the synthesis of wild-type Ad3 late proteins during co-infections of monkey cells with Ad2hr400 and Ad3. Restriction enzyme analysis of the genomes of all the host-range mutants

showed that none contained major alterations. The mutation responsible for the extended host range was physically mapped by marker rescue experiments using isolated restriction enzyme fragments of the mutants to transfer the new phenotype to wild-type adenovirus. The alteration in each of the five mutants was located in a region (coordinates 62-70.7; coordinates 62-68 for Ad5hr404) that encodes predominantly the 72K DNA binding protein. More detailed mapping using Ad2hr400 fragments placed the mutation entirely within the 72K. (38 refs)

79-5810 Isolation and Characterization of a Specific Deletion Mutant of Human Adenovirus Type 2. (Eng) Van Roy, F. (Lab. Molecular Biology, State Univ. Ghent, Ledeganckstraat 35, B-9000 Ghent, Belgium); Engler, G.; Fiers, W. *Virology* 96(2): 486-502; 1979.

A specific deletion mutant of human adenovirus type 2 (dl-Ad2), detected when pools of wild-type Ad2 were grown at a high multiplicity of infection in HeLa cells, was isolated and characterized. dl-Ad2 was enriched when the defective Ad2-simian virus 40 (SV40) hybrids of the Ad2**HEY population were cloned in monkey cells in the presence of an added excess of wild-type Ad2. Electron microscope heteroduplex analysis and restriction endonuclease examination established the Ad-specific nature of the dl-Ad2 DNA and revealed a single, homogeneous deletion of about 0.08 to 0.09 fractional genome length situated between 0.78 and 0.87 Ad2 map units. This genome structure is very similar to that of several other incomplete adenoviruses described previously. The deleted segment encompasses one of the four early genome regions of Ad2. dl-Ad2 particles are not infectious in both human and monkey cells, although the mutant DNA is replicated in these cell types. dl-Ad2 is able to interfere efficiently with SV40 DNA replication in coinfecting monkey cells. Furthermore, virus populations consisting exclusively of Ad2**HEY hybrid viruses and dl-Ad2 "helper" viruses can be cloned, indicating that dl-Ad2 can complement sufficiently for the large Ad2 DNA deletion in the Ad2**HEY hybrid genomes. (42 refs)

79-5811 Multiple Discrete Sites for Premature RNA Chain Termination Late in Adenovirus-2 Infection: Enhancement by 5,6-Dichloro-1- β -D-ribofuranosylbenzimidazole. (Eng) Fraser, N. W. (Wistar Inst., 36th St. at Spruce, Philadelphia, PA 19104); Sehgal, P. B.; Darnell, J. E. *Proc Natl Acad Sci USA* 76(6): 2571-2575; 1979.

The oligonucleotide composition of short adenovirus 2 (Ad2)-specific RNA that accumulates late in infection is described. Discrete-sized short RNA chains that contained the distinctive oligonucleotides, including the 5'-capped oligonucleotide, characteristic of the first 600 nucleotides of the Ad2 large, late, rightward-reading transcriptional unit (16.4-99) accumulated in Ad2-infected HeLa cells. In the presence of 5,6-dichloro-1- β -D-ribofuranosylbenzimidazole, the accumulation of these chains was enhanced, as was the accumulation of short chains from a neighboring rightward-reading transcriptional unit (3.0-10.7). These short chains appeared to represent prematurely terminated transcripts. Late in infection, there was a marked increase in RNA synthesis, including that of prematurely terminated short chains, from the large late transcriptional unit. This suggests that the increase in transcription and messenger RNA production from this region late in infection is not due to reduced "attenuation" of RNA synthesis. (35 refs)

79-5812 Affinity of Oncogenic Adenoviruses for Lysosomes in Infected Cells. (Eng) Ogier, G. (Unite de Virologie Fondamentale et Appliquee, INSERM, Groupe de Recherche 33 1/m CNRS, 1, Place de Professeur Joseph Renaut, 69371 Lyon Cedex 2, France); Gazzolo, L.; Lyon, M.; Chardonnet, Y. *Microbios Lett* 8(31/32): 133-137; 1978.

The distribution of virus particles in various cell compartments during penetration of adenoviruses (Ad) 4 and 31 into HeLa cells was studied, and the results are presented together with those of previously reported similar studies of Ad 1, 4, 5, 7, 12 and 31. Ad 7, 31 (both subgroup B), and 12 (subgroup A) are oncogenic for newborn hamsters, while Ad 1 and 5 (subgroup C) are not. Ad 4 (subgroup C) is not oncogenic but shares many features with subgroup B serotypes. Electron microscopic examination 30-120 min following infection of HeLa cells with Ad 4 or Ad 31 at 10-100 plaque-forming units (PFU)/cell demonstrated that 32%-44% of these viral particles were sequestered in the lysosomes, thus demonstrating that there are quantitative differences in Ad particle sequestration in lysosomes for the different serotypes; 5%-10% sequestration has been reported for Ad 1 and 5, while 65%-82% has been demonstrated for Ad 7 and 12. These results indicate that viral particles nononcogenic for newborn hamsters have a higher capacity to release into the cytoplasm from the phagocytosing vacuoles before their fusion with lysosomes. Most of the oncogenic particles do not escape from the phagocytosing vacuoles and are found trapped in the lysosomes, where they remain infectious. It is suggested that the passage of oncogenic serotypes through lysosomes might be a necessary step for the expression of their transforming ability. (13 refs)

79-5813 Pre-Early Adenovirus 5 Gene Product Regulates Synthesis of Early Viral Messenger RNAs. (Eng) Berk, A. J. (Dept. Microbiology, LSB 5034, Univ. California, Los Angeles, CA 90024); Lee, F.; Harrison, T.; Williams, J.; Sharp, P. A. *Cell* 17(4): 935-944; 1979.

The S1 nuclease gel technique was used to examine the expression of early messenger RNA (mRNA) after infection of HeLa cells with adenovirus 5 host range (Ad5) hr group I and II mutants. The Ad5 hr group II mutants stimulated the synthesis of a wild-type pattern of early mRNAs. In contrast, infection of HeLa cells with Ad5 hr group I mutants gave rise to only two early mRNAs, which mapped from 1.5-4.4 units, or in the same region as the Ad5 hr group I mutants. Since infection of HeLa cells with Ad5 hr group I mutants was defective for synthesis of cytoplasmic mRNAs complementary to three early regions in the right half of the genome and to the early region 4.5-11.0 units, nuclear RNA from these cells was also analyzed for the presence of precursor RNA chains using the S1 nuclease gel technique. Nuclear precursors were not detected in Ad5 hr group I-infected HeLa cells, suggesting that the gene product defective in these mutants is required by synthesis of stable nuclear RNA from the three early regions in the right half of the genome and from the early region 4.5-11.0 units. (52 refs)

79-5814 Location of Additional Early Gene Sequences in the Adenoviral Chromosome. (Eng) Galos, R. S. (Dept. Biological Sciences, Carnegie-Mellon Univ., Pittsburgh, PA 15213); Williams, J.; Binger, M. H.; Flint, S. J. *Cell* 17(4): 945-956; 1979.

Regions in the type C human adenovirus (Ad) genome expressed during the early phase of productive infection were studied using

marker-rescue and hybridization techniques. Ad5 DNA-terminal protein complex was used to infect 293 cells, and mutant DNA-protein complex was used in marker rescue. The H5ts36, H5ts149, and H5ts69 mutations were mapped between 18.5 and 22.0 units on the Ad5 genome; all three early ts mutants are classified within complementation group N. Saturation hybridization experiments revealed in the Ad2 genome two sets of I strand sequences to the left of position 26.5 units that are complementary to early cytoplasmic RNA. RNA sequences complementary to the IVa₂ gene were located on the 8.0-17.0-unit fragment, and four units of the I strand were located between 18.5 and 23.24 units. Early cytoplasmic RNA was fractionated on oligo(dT)-cellulose columns, and the Ad sequences complementary to different single-stranded DNA probes were assayed. RNA sequences hybridizing to the two I strand regions above included some carrying poly(A). The RNA sequences complementary to the I strand between 11 and 14 units and between 19.8 and 23.24 units were calculated to be present at concentrations of about 20 and 30 copies/cell, respectively. Experiments in which HeLa cells were infected at unequal input multiplicities with Ad5 wild-type and temperature-sensitive mutants suggested that the H5ts36 gene codes for a product, possibly of catalytic function, which is either present or required at a very low level early in infection. (53 refs)

79-5815 Phenotypic Properties and Tumor Promoter-induced Alterations in Rat Embryo Cells Transformed by Adenovirus. (Eng) Fisher, P. B. (Div. Environmental Sciences, Inst. Cancer Res., Coll. Physicians and Surgeons Columbia Univ., 701 W. 168th St., New York, NY 10032); Goldstein, N. I.; Weinstein, I. B. *Cancer Res* 39(8): 3051-3057; 1979.

The phenotypic properties of seven clones of secondary rat embryo cells (SREC) transformed by a temperature-sensitive mutant of human adenovirus type 5 (H5ts125) were analyzed to determine whether transformants obtained from cultures treated with a chemical carcinogen prior to virus infection had a different phenotype than those obtained from cultures treated with virus alone. The effects of prolonged serial passage and the effects of exposure of the clones to 12-O-tetradecanoylphorbol-13-acetate (TPA) on the expression of several markers of transformation were also determined. Compared with normal SREC, most of the transformants had a reduced population-doubling time, increased saturation density, reduced serum requirement, increased plasminogen activator production, reduced large external transformation-sensitive protein, increased lectin agglutinability, and decreased anchorage dependence (ie, growth in agarose and agar). Prolonged serial passage of the transformants led to a spontaneous increase in cloning efficiency in agar. There was no consistent difference between the phenotypes of transformants obtained from cultures treated with carcinogen plus virus or those of transformants obtained with virus alone, although the former transformants appeared to express anchorage independence at earlier subpassages. The most striking finding was that TPA appreciably enhanced the growth in agar of all transformants. Two early passage-transformed clones grew in agar only in the presence of TPA. The tumor promoter also increased the saturation densities and enhanced the cloning efficiencies in liquid medium of most of the transformants. These effects were not seen with normal SREC. These results suggest that following adenovirus transformation, there is a spontaneous progression in the expression of markers of transformation and that phorbol ester tumor promoters can accelerate this process. (45 refs)

79-5816 Cleavage Maps of Weakly Oncogenic Human Adenovirus Type 7 DNA by Restriction Endonuclease

BamHI and SalI. (Eng) Yoshida, K. (Dept. Molecular Biology, Cancer Res. Inst., Sapporo Medical Coll., Sapporo 060, Japan); Sekikawa, K.; Fujinaga, K. *Tumor Res (Sapporo)* 13: 14-19; 1978.

Weakly oncogenic human adenovirus type 7 DNA (Grider strain) was cleaved into 10 and 3 specific fragments by the restriction endonucleases *BamHI* and *SalI*, respectively. These specific fragments were mapped on the adenovirus type 7 genome by analyzing the partial digestion products and by DNA-DNA hybridization. (12 refs)

79-5817 Analysis of Human Cancer DNA's for DNA Sequences of Human Adenovirus Serotypes 3, 7, 11, 14, 16, and 21 in Group B. (Eng) Wold, W. S. (Inst. Molecular Virology, St. Louis Univ. Sch. Medicine, St. Louis, MO 63110); Mackey, J. K.; Rigden, P.; Green, M. *Cancer Res* 39(9): 3479-3484; 1979.

Molecular hybridization with highly radioactive adenovirus 7 (Ad7) or adenovirus 11 (Ad11) DNA was used to analyze 125 human cancer DNA's and 37 normal tissue DNA's for Group B Ad sequences. Hybridization of Ad7-radiolabeled DNA with DNA's from an Ad7-induced primary hamster tumor and from two cell lines (5728 and Ad7 P-cell) established from Ad7-induced hamster tumors indicated that there were multiple copies per cell of 17%, 30%-36%, and 20%, respectively, of the Ad7 genome. No Ad7 sequences were detected in DNA's from 16 normal human lung tissues, 18 normal digestive tissues, 34 cancers of the respiratory system, 19 cancers of the digestive system, 11 cancers of the urinary system, 5 cancers of the genital system, 3 cancers of the breast, or 6 Hodgkin's lymphomas. No Ad11 sequences were detected in DNA's from 9 bladder carcinomas, 10 prostate carcinomas, 24 renal carcinomas, 3 renal cell carcinomas, 3 Wilms' tumors, or 2 normal kidneys. The data provide evidence but not formal proof that none of the human cancers analyzed were induced by Group B Ad's. (46 refs)

79-5818 Revertants of Adenovirus Type-12-transformed Hamster Cells Have Lost Part of the Viral Genomes. (Eng) Groneberg, J. (Inst. Genetics, Univ. Cologne, Cologne, W. Germany); Doerfler, W. *Int J Cancer* 24(1): 67-74; 1979.

Eighteen morphological revertants isolated from line T637, which was derived from BHK21 cells (subline B3) by transformation with adenovirus type 12 (Ad12), were characterized. The T637 cells were round and epithelioid, but the revertant cells were fibroblasts. The revertants arose spontaneously and could be enriched by letting the T637 culture grow to very high density. The T637 cells detached from the plastic surface, whereas the revertants stayed attached and could then be cloned. The morphological revertants differed from the B3 and T637 lines with respect to saturation density, growth rate, agglutinability by plant lectins, and uptake of low-mol-wt compounds. The revertants were all tumor-antigen negative, but they reacted with anti-LETS serum (antisera against the large, external, transformation-sensitive protein). The B3 and T637 cells were LETS-negative. The revertants exhibited a pseudodiploid karyotype. All 18 revertants could be transplanted into 4-wk-old Syrian hamsters, although most of them grew less rapidly than the B3 cells. The patterns of integration of Ad12 DNA were investigated by a DNA-DNA hybridization technique. Four of the revertant lines appeared to have lost almost all their viral DNA sequences; the other revertant lines

lacked several of the viral DNA sequences present in the T637 line, which contained multiple copies of the viral genome. Upon superinfection of all the lines with Ad2, Ad2 replication was inhibited in T637 cells, but Ad2 grew as efficiently or even more so in the revertants than in the B3 line. (19 refs)

79-5819 A Marsupial Oncovirus? (Eng) Hamilton, R. C. (Commonwealth Serum Lab., 45 Poplar Road, Parkville, Victoria 3052, Australia); MacGregor, A.; Pye, D. *J Gen Virol* 44(2): 535-539; 1979.

The development of a virus-like particle observed in two continuous cell lines derived from the marsupial, *Sminthopsis crassicaudata* (fat-tailed dunnart), was investigated. The development of the particle was similar to the development of D-type oncoviruses. Initially, a crescent of nucleoid material was observed near the nucleus in the region of the Golgi apparatus. This crescent developed into a doughnut-shaped A-type particle, which migrated through the cytoplasm toward the cell membrane, where it began to bud. Budding took place either into a cytoplasmic vacuole or from the cell membrane. The particle continued moving until it consisted of a circular knob connected to the cell by an isthmus of cytoplasm, which elongated and narrowed until the particle broke free from the cell. Only enveloped A-type particles were observed; no mature B-type, C-type or D-type particles were detected. (20 refs)

79-5820 Type C Virus and Immunoglobulin A Production by Murine Myeloma MOPC-315: Two Independent Activities. (Eng) Gazit, A. (Dept. Human Microbiology, Sackler Sch. Medicine, Tel-Aviv Univ., Tel-Aviv, Israel); Yaniv, A.; Halperin, D.; Ben-Efraim, S. *Infect Immun* 25(2): 569-573; 1979.

The suspected correlation between cessation of type C virus production and cessation of immunoglobulin secretion by murine myeloma cells was studied using immunoglobulin A-producing (IAP) and -non-producing (NP) variants of the murine myeloma MOPC-315. Complementary DNA (cDNA) prepared from the virus particles released by NP cells was annealed at identical Crt values to 70S RNAs extracted from viral particles from both NP and IAP cells. Both RNA species followed the same hybridization kinetics curve and 87% final hybridization, suggesting that the nucleotide sequences of the viruses shared extensive homology. This homology was further substantiated by similar melting profiles and identical thermal stability values (approx 90°C). The two myeloma variants also released similar levels of virus particles. Cytoplasmic RNAs from both IAP and NP cells annealed to the same extent and with the same kinetics as cDNA prepared from NP virus, demonstrating that the viral genomes were equally transcribed in the two plasmacytomas. The data indicate that the amount of extracellular viral particles, as well as the level of viral gene expression occurring in the myeloma cells are not affected by the loss of cell capacity to secrete IgA protein. (23 refs)

79-5821 Characterization of a Type-C Virus Produced by Cocultures of Human Leukemic Bone-Marrow and Fetal Canine Thymus Cells. (Eng) Smith, R. G. (Lab. Tumor Cell Biology, NCI, Bethesda, MD 20014); Nooter, K.; Bentvelzen, P.; Robert-Guroff, M.; Harewood, K.; Reitz, M. S.; Lee, S. A.; Gallo, R. C. *Int J Cancer* 24(2): 210-217; 1979.

The putative human helper virus SKA-21/A204V, isolated in 1977 from human leukemic bone marrow cells following coculture with normal fetal canine thymus cells (Cf2th), was characterized with respect to its major viral core protein, reverse transcriptase, and nucleic acid sequences. The analyses show that this virus is closely related to the C-type woolly monkey virus simian sarcoma virus-1/simian sarcoma associated virus-1, but contains no detectable determinants, either genetic or immunologic, that are related to Rauscher murine leukemia virus or to the baboon endogenous virus M7. (52 refs)

pying poliovirus RNA, it was first purified by phosphocellulose chromatography and further purified 60-fold by poly(U)-Sephadex chromatography. The poly(U) polymerase activity copurified with the replicase activity. Although less-pure replicase fractions copied a variety of RNA's, purer fractions responded better to poliovirus RNA than to other viral RNA's. Even the less-pure fractions made a specific copy of the added template, as shown by hybridization of the product to its template RNA but not to other RNA's. Among homopolymers, only poly(A)-oligo(U) was copied by the replicase; other primed homopolymer templates were inactive. (23 refs)

79-5822 Poliovirus Replicase: A Soluble Enzyme Able to Initiate Copying of Poliovirus RNA. (Eng) Dasgupta, A. (Dept. Biology, Massachusetts Inst. Technology, Cambridge, MA 02139); Baron, M. H.; Baltimore, D. *Proc Natl Acad Sci USA* 76(6): 2679-2683; 1979.

The soluble phase of the cytoplasm of poliovirus-infected HeLa cells contains an enzyme activity able to copy RNA without an added primer. This replicase activity is absent from uninfected cells. To determine whether this soluble, poliovirus-specific, poly(U) polymerase activity corresponds to an enzyme also capable of co-

- 79-5823** Correlation of Immunogenetic and Histological Changes in Immuno-deficient Mutant hr/hr Mice. (Eng) Reske-Kunz, A. B. (Memorial Sloan-Kettering Cancer Center, 1275 York Avenue, New York, NY 10021); Scheid, M. P.; de Sousa, M.; Boyse, E. A. *Adv Exp Med Biol* 114: 55-58; 1979.

The number of cells expressing the Lyt-1 and Lyt-123 surface phenotypes was studied in HRS/J mice, which carry the hairless (hr) mutation associated with premature immunodeficiency and a higher incidence of leukemia. At approx 3-3.5 mo of age, hr/hr homozygotes showed a highly significant increase in Lyt-123 cells and an equally significant decrease in Lyt-1 cells, compared with age-matched, hr/+ littermates. These changes were paralleled by a scarcity of splenic germinal centers and the development of abnormal lymphoid cell aggregates. Further findings suggested that these changes also occurred in the heterozygotes at a later age. (6 refs)

- 79-5824** Prolongation of Survival Time of Mice Inoculated with Myeloid Leukemia Cells by Inducers of Normal Differentiation. (Eng) Honma, Y. (Dept. Chemotherapy, Saitama Cancer Center Res. Inst., Ina-machi, Kitaadachi-gun, Saitama-362, Japan); Kasukabe, T.; Okabe, J.; Hozumi, M. *Cancer Res* 39(8): 3167-3171; 1979.

Studies were conducted to determine whether the leukemogenicity of sensitive mouse myeloid leukemia (M1) cells is affected by treatment with inducers of cell differentiation, whether resistant and sensitive M1 cells differ in immunogenicity, and whether the possible decrease of leukemogenicity caused by inducers can be separated from enhancement of T-lymphocyte-mediated immune responses. Inducers of cell differentiation [certain proteins, bacterial lipopolysaccharides (LPS), or glucocorticoids] significantly enhanced the survival times of inbred SL mice inoculated with sensitive cells, but they scarcely affected the survival times of mice inoculated with resistant cells. Some mice inoculated with the sensitive cells and treated with LPS did not develop leukemia. Sensitive and resistant clone cells contained similar common tumor-associated surface antigens. Treatment with LPS was also effective in athymic nude BALB/c mice inoculated with the sensitive M1 cells. LPS increased the survival times of these mice, which suggests that the inhibitory effect of LPS is not directly involved in T-lymphocyte-mediated immune responses. LPS and glucocorticoid significantly stimulated differentiation of the sensitive cells cultured in a diffusion chamber in vivo, but they had little effect on the differentiation of resistant cells. These results suggest the possibility of treating, with partial success, leukemia in vivo with differentiation inducers. (31 refs)

- 79-5825** Thymic Dependence of Cell-mediated Immunity to Avian Sarcomas in Chickens. Immunological Characterization of a Nonvirion Antigen in Virus-infected Cells. (Eng) Wainberg, M. A. (Lady Davis Inst. Medical Res., Jewish General Hosp., 3755 Cote Sainte Catherine Rd., Montreal, Quebec H3T 1E2, Canada); Beiss, B.; Wahi, R.; Israel, E. *Cell Immunol* 45(2): 344-355; 1979.

Cell-mediated immunity in chickens bearing tumors induced by avian retroviruses was studied in a peripheral lymphocyte stimulation assay. To determine whether virion or nonvirion antigen(s) elicited a blastogenic response, lymphocytes of normal and tumor-bearing chickens were exposed to supernatant fluids of avian retrovirus-infected chicken embryo fibroblast cells and to the plasma of birds that had been inoculated with avian myeloblastosis virus. The results indicated that the antigenic activity being measured was virus group specific, cell transformation independent, and nonvirion in nature. Paradoxically, the expression of such antigen(s) was restricted to cells that actively synthesized progeny avian retrovirus particles; it was absent in mammalian non-producer cells that had been transformed by avian sarcoma viruses. The ability to respond immunologically to such antigen(s) was present in birds inoculated with either leukosis or sarcoma viruses. Thymectomy, but not bursectomy, stimulated tumor growth and abolished the immune responsiveness of sensitized lymphocytes in this system. (36 refs)

- 79-5826** Production of Lymphoid Tumors in Hamsters by Direct Implantation of Human Umbilical Cord WBC. II. Analysis of Adenoma Structural Cells. (Jpn) Matsuda, Y. (Second Dept. Internal Medicine, Okayama Univ. Medical Sch., Okayama, Japan). *Acta Haematol Jpn* 42(3): 368-376; 1979.

Human umbilical cord WBC were transplanted intraarterially in newborn hamsters, and the resulting lymphoid tumor cells were separated into human and hamster cells and then subdivided by specific anti-human and anti-hamster rabbit sera. Human cells comprised approx 79.6% of the lymphoid tumor cells, and hamster cells 18.7%. Approx 23.3% of the human cells were erythrocyte rosette (ER)-forming T cells, 1.7% were human Ig-positive B cells, and the rest had neither of these two markers. The transformed cells that were anti-human serum-positive were divided into two main types: (1) ER-positive and Ig-negative, and (2) ER-negative and Ig-negative. A small number of these cells were also ER-negative and Ig-positive. Cells with both a negative and positive response were also found among the hamster cells. These results suggest that there is a correlation between lymph node enlargement and the graft-vs-host reaction. (26 refs)

- 79-5827** Origin Of Chronic Myelocytic Leukemia in a Precursor of Pre-B Lymphocytes. (Eng) LeBien, T. W. (Dept. Lab. Medicine and Pathology, Univ. Minnesota, Box 609 Mayo, 420 Delaware St. SE, Minneapolis, MN 55455); Hozier, J.; Minowada, J.; Kersey, J. H. *N Engl J Med* 301(3): 144-147; 1979.

The malignant cells of three patients with Philadelphia chromosome-positive chronic myelocytic leukemia in blast crisis were characterized immunologically. The patients were three women, aged 41, 43, and 3 yr, respectively. Cells from all three patients were negative for the sheep RBC receptor, surface immunoglobulin, Fc receptors, and C3 complement receptors. However, all were positive for an "acute lymphoblastic leukemia-associated antigen" and human p23,30 (immune-associated antigen-like) antigen. Two patients were positive for cytoplasmic

IgM: the cells of one were also positive for cytoplasmic kappa chains, and the cells of the other were positive for cytoplasmic lambda chains. (23 refs)

- 79-5828 Subset Derivation of T-Cell Acute Lymphoblastic Leukemia in Man. (Eng) Reinherz, E. L. (Div. Tumor Immunology, Sidney Farber Cancer Inst., Boston, MA 02115); Nadler, L. M.; Sallan, S. E.; Schlossman, S. F. *J Clin Invest* 64(2): 392-397; 1979.

To determine whether human T-cell acute lymphoblastic leukemia (T-ALL) cells belong to one or another T-cell subset, cell-surface phenotyping was performed on tumor populations from 25 patients with T-ALL. Tumor cells from these 25 individuals were either TH₁ or TH₂, but not both. Five of 25 patients had TH₁ T-ALL cells. These TH₁ tumor populations were found exclusively in children and often without an accompanying thymic mass. TH₂ T-ALL, in contrast, occurred in both children and adults and was almost always associated with thymic enlargement. Although children with TH₁ T-ALL had as high or higher peripheral blast counts on presentation than their TH₂ T-ALL counterparts, overall survival was greater for the TH₁ group (>36 mo) than the TH₂ group (<12 mo). These studies demonstrate that T-cell leukemias in humans arise from distinct T-cell subsets and that cell-surface characterization of T-cell malignancies may provide useful clinical data related to prognosis. - 79-5829 In Vivo Activity of Lymphocytes Sensitized in Vitro by Antigen-fed Macrophages: Inhibition by Lymphoma Growth. (Eng) Treves, A. J. (Dept. Radiation and Clinical Oncology, Inst. Oncology-Hadassah Univ. Hosp., Jerusalem, Israel); Feldman, M.; Honsik, C.; Kaplan, H. S. *Adv Exp Med Biol* 114: 629-634; 1979.

The possibility that effector lymphocytes induced in vitro by radiation leukemia virus (RadLV)-fed macrophages may affect tumor growth in vivo by recruitment of the host defense response was studied using specific pathogen-free (C57BL/Ka x BALB/c)F₁ mice. Spleen lymphocytes which had been sensitized by RadLV-fed macrophages were injected ip into normal mice 4 days prior to the injection of BL/VL₃ lymphoma cells. Compared with control lymphocytes, the sensitized lymphocytes protected against lymphoma growth. The 4-day time interval was required for this protective activity. Whereas irradiation of the lymphocytes did not affect their protective activity, irradiation of the recipient mice abolished the protective response. Spleen cells which had been sensitized directly against BL-5 cells (a noninfected line derived from C57BL/Ka embryo fibroblasts) protected recipient mice against tumor development; this protection was weaker than that conferred by macrophage-mediated sensitized lymphocytes and was completely abolished by irradiation of the sensitized cells. - 79-5830 Tumor-specific Immunity Induced by Somatic Hybrids. II. Elicitation of Enhanced Immunity Against the Parent Plasmacytoma. (Eng) Kim, B. S. (Dept. Microbiology-Immunology, Northwestern Univ. Medical and Dental Schs., Chicago, IL 60611). *J Immunol* 123(2): 739-744; 1979.

Hybrid cells derived from the fusion of a BALB/c plasmacytoma (TEPC-15) and L cells (C3H origin) were used to stimulate tumor-

specific immunity against the parental plasmacytoma cells. Live hybrid cells induced tumor-specific immunity against TEPC-15 more effectively than mitomycin-treated hybrid or TEPC-15 tumor cells. Adoptive transfer of immunity with spleen cells of mice immunized with hybrid cells was also more effective than that with mitomycin-treated tumor cells. The immunity induced by the hybrid cells was specific to the TEPC-15 tumor, because the mice that received immune spleen cells were not protected against challenge with either HOPC-8 or McPC-603 plasmacytomas. T cells were primarily responsible for the transfer of specific immunity based on the sensitivity of immune cells to anti-Thy 1.2 and complement. Mice that had established solid tumors were treated with 5×10^7 spleen cells to evaluate the therapeutic value of the hybrid-induced immune cells. Tumors in mice that received immune cells gradually regressed over a 40-day period, whereas tumors in control mice continued to grow. These results suggest that a rearrangement of tumor-specific transplantation antigens on allogeneic hybrid cells can enhance their immunogenicity. (36 refs)

- 79-5831 Tumor-specific Immunity Induced by Somatic Hybrids. I. Lack of Relationship Between Immunogenicity and Tumorigenicity of Selected Hybrids. (Eng) Kim, B. S. (Dept. Microbiology-Immunology, Northwestern Univ. Medical Sch., Chicago, IL 60611); Liang, W.; Cohen, E. P. *J Immunol* 123(2): 733-738; 1979.

The morphology, tumorigenicity, and immunogenicity of three representative hybrid clones derived from the fusion of TEPC-15 plasmacytoma cells of BALB/c mice with L cells of C3H mice were compared. One clone (LTC-1) showed a morphology intermediate to that of either parental cell and possessed the highest tumorigenic and immunogenic properties. The other two clones displayed a flat morphology that differed significantly from that of either parent. One of these two, LTC-4, eventually induced tumors in some (BALB/c x C3H)F₁ mice but failed to stimulate protective immunity against TEPC-15 tumor cells in BALB/c mice. The other hybrid clone, LTC-2, had a very flat morphology and did not induce tumors, although it was capable of stimulating a significant level of tumor immunity. Histologically, all tumors induced by the hybrid cells were fibrosarcomas rather than plasmacytomas. These results indicate that the morphology of hybrid cells may be correlated with their tumorigenicity as well as with the histologic appearance of the tumors they produce. In addition, the degree of tumorigenicity of individual hybrid clones does not correspond to their immunogenicity in the host, suggesting that major antigens responsible for immunogenicity may not play an important role in tumor induction. (23 refs)

- 79-5832 Effect of Exposure to a Heterogeneous Adenocarcinoma on the Mineral Oil Induction of Plasma Cell Tumors in BALB/c Mice. (Eng) Harkonen, W. S. (Dept. Medicine, Univ. Minnesota Medical Center, Minneapolis, MN 55455); Theologides, A. *IRCS Med Sci (Cancer)* 7(6): 291; 1979.

Exposure to transplanted heterogeneous adenocarcinoma tissue increased the incidence of mineral oil-induced plasma cell tumors in BALB/cby mice. This effect appeared to be mediated whether the mice experienced actual growth of the transplanted tumor, or whether the graft was rejected. (6 refs)

- 79-5833 Release of Immature Cells from the Thymus During Solid Tumor Growth: Identification by Assay of TdT

Activity. (Eng) Small, M. (Dept. Cell Biology, Weizmann Inst. Science, Rehovot, Israel); Lasser-Weiss, M.; Daniel, V. *J Immunol* 123(1): 259-262; 1979.

The hypothesis that as tumor growth progresses, early thymocytes (TC's) with tumor-enhancing activity are released from the thymus and accumulate in the periphery where they may counteract the activity of tumor-inhibiting T cells was tested. Experiments were undertaken to determine whether artificial introduction of TC's into the periphery can cancel tumor inhibition by sensitized spleen cells during the period when the splenocytes manifest antitumor reactivity and whether immature cells are naturally released from the thymus and accumulate in the spleen as tumor growth progresses and the antitumor response fades. Three groups of C3H/eb mice were challenged sc with 5×10^4 syngeneic fibrosarcoma cells plus: no additional treatment, 5×10^6 nucleated spleen cells from tumor-bearing mice in the tumor-inhibiting period, or 5×10^6 nucleated spleen cells from tumor-bearing mice during the tumor-inhibiting period that had been injected with TC's 24 hr earlier. Control mice received tumor cells alone. The spleen cells came from mice that had received 5×10^4 fibrosarcoma cells 3.5 wk before becoming spleen donors. The TC's were taken during repopulation of cortisone-depleted thymuses, 48 hr after injection of 5 mg hydrocortisone acetate into donor mice. Compared with controls, tumor growth was inhibited in mice receiving sensitized spleen cells, but the inhibiting activity was abolished by the injection of TC's. Thus, TC that reached the periphery by artificial means neutralized the activity of the tumor-inhibiting cells. To determine whether premature TC release occurs naturally, T cells usually found in the thymus and not in the spleen were identified by assaying for the thymus cell marker enzyme terminal deoxynucleotidyl transferase (TdT) in populations of TC's and spleen cells from normal or tumor-bearing C3H/eb mice, in both the tumor-inhibiting and tumor-enhancing periods. Significant TdT activity was observed in TC's but not in spleen cells from normal mice, it was found at a low level in spleen cells tested during the early tumor-inhibiting stage, and it was considerably elevated in spleen cells tested during the later tumor-enhancing stage. These results suggest that recently released TC's accumulate in the spleen during the progression of tumor growth in parallel with the gradual eclipse of antitumor reactivity in the spleen cells. (24 refs)

79-5834 Cell-mediated Immune Response to Syngeneic Ultraviolet-induced Tumors. II. The Properties and Antigenic Specificities of Cytotoxic T Lymphocytes Generated In Vitro Following Removal from Syngeneic Tumor-immunized Mice. (Eng) Daynes, R. A. (Dept. Pathology, Univ. Utah Medical Center, Salt Lake City, UT 84132); Fernandez, P. A.; Woodward, J. G. *Cell Immunol* 45(2): 398-414; 1979.

The immune responses of C3Hf mice to syngeneic fibrosarcomas induced by UV light or methylcholanthrene (MC) were measured in vitro by the ability of cytotoxic T lymphocytes (CTL) from immunized animals to kill ^{51}Cr -labeled tumor targets in a 6-hr assay. The CTL were generated by the in vitro culturing of draining popliteal lymph node (DLN) cells derived from animals that were footpad immunized 8 days previously. CTL activity was generated using DLN cells from both normal (UV tumor-resistant and UV-exposed (UV tumor-susceptible) C3H mice. The kinetics of CTL generation between these two groups, however, was different in that the lymphocytes from normal animals appeared to differentiate into CTL faster than the lymphocytes from the UV-irradiated mice. The in vitro generation of CTL activity was found to be extremely radiosensitive and was also inhibited by the presence of viable tumor cells within the cell culture. Once generated, the CTL

were extremely insensitive to the effects of γ radiation. The CTL is a T lymphocyte that appears to be immune-associated antigen-negative. The CTL derived from mice immunized to syngeneic UV- or MC-induced tumors were capable of expressing cross-reactive non-major histocompatibility complex-restricted killing of multiple tumor targets. Cold cell inhibition experiments confirmed the presence of cross-reactive determinants on various tumors and also established the presence, within a single CTL preparation, of effector cells with specificity for both the unique tumor-specific transplantation antigens as well as the common (cross-reactive) tumor-associated antigens. (27 refs)

79-5835 Cytolytic Antibodies to Methylcholanthrene-induced Sarcomas Elicited by Immunization of Syngeneic Mice. (Eng) Merino, F. (Dept. Experimental Medicine, Instituto Venezolano de Investigaciones Cientificas, Apartado 1827, Caracas, Venezuela); Abeyounis, C. J.; Milgrom, F. *Eur J Cancer* 15(6): 829-835; 1979.

The specificity of the antibodies produced by immunizing syngeneic animals with chemically induced tumors and the reported cross-reactivity of these tumors with tumors of different histogenetic origin, such as lymphomas, were analyzed. Cytolytic antibodies were tested in the sera of C3H/HeHa mice grafted twice with a solid syngeneic methylcholanthrene (MC)-induced sarcoma or immunized with an ascitic form of the MC sarcoma. These sera reacted with syngeneic tumor cells as well as with normal and malignant allogeneic cells. Absorption experiments suggested that the antisera contained two populations of antibodies. One population combined with antigen(s) shared by the MC sarcomas of C3H/HeHa mice, the normal and malignant cells of C3H/St mice, and the normal and malignant cells of C57BL/6 mice. The other antibody population failed to react with the cells of C57BL/6 mice, but it reacted with C3H/HeHa MC sarcoma cells and with normal and malignant cells of C3H/St origin. (24 refs)

79-5836 Induction of Transplantation Resistance with Soluble Simian Virus 40-induced Hamster Tumor-specific Transplantation Antigen. (Eng) Coggin, J. H. (Univ. South Alabama, Coll. Medicine, Dept. Microbiology and Immunology, Mobile, AL 36688). *Cancer Res* 39(8): 2952-2959; 1979.

Multiple injections of 3 M KCl extracts of simian virus 40 (SV40)-induced Syrian golden hamster sarcoma cells did not inhibit tumor growth in syngeneic hamsters following homologous tumor challenge. When a single injection of this extract was administered in the range of 0.5 mg of antigen protein, tumor appearance was delayed significantly, and a significant number of challenge animals failed to develop tumors in two of three experiments. A single injection of the tumor cell extract generally conferred to 20%-40% permanent protection, always with a marked delay in tumor appearance. The immunity was specific in that immunization with normal muscle extracts or heterologous tumor challenge did not protect against or delay tumor appearance. Higher or lower amounts of homologous, soluble tumor transplantation antigen given in a single injection were either without effect or promoted tumor development. The resistance observed in animals receiving a single dose of soluble tumor antigen could only be detected if the hamsters were challenged with 5×10^6 tumor cells. Challenge with only 10^4 tumor cells did not lead to the detection of resistance. The immunity induced by a single optimal dose of tumor antigen could be transferred to normal, uninjected hamsters at 20 days postsensitization with lymph node cells, but not with

peritoneal exudate cells from injected donors, suggesting that the immunity detected in animals immunized with soluble tumor extracts was cell-mediated. These data indicate that antigen dose, regimen of administration to the host, and the challenge level used to detect transplantation resistance are all important parameters to consider when using cell-free, tumor-associated transplantation antigens. They strongly support and extend an earlier report derived in another model with a chemically induced tumor. (28 refs)

- 79-5837 Role of Regional and Distant Lymph Nodes in Rejection of Feline Sarcoma Virus-induced Tumors in Sheep. (Eng) Theilen, G. H. (Dept. Surgery, Section Clinical Oncology, Sch. Veterinary Medicine, Univ. California, Davis, CA 95616); Pedersen, N. C.; Higgins, J. *J Natl Cancer Inst* 63(2): 389-400; 1979.

The sequential immunologic responses that occur over a 30- to 40-day span in lymph nodes regional and distant to feline sarcoma virus (FeSV)-induced tumors were investigated in nine crossbred Corridale sheep. Following injection of FeSV-transformed allogeneic or autochthonous fibroblasts into the lower leg, small tumors developed at the site of inoculation and subsequently regressed. Efferent lymph from the regional popliteal nodes and distant nodes in the same host was collected for periods up to 40 days after tumor cell inoculation. The cell response in the efferent lymph of the stimulated node was the same regardless of whether the inoculum consisted of autochthonous or allogeneic FeSV-transformed sheep cells. There was a rapid rise in total lymphocytes leaving the regional node, beginning at 3 days and peaking at 6-8 days postinoculation. On days 6-8 postinoculation, lymphoblasts ranging from 25% to 40% of the total cell output appeared in the regional lymph. The cell population in lymph from distant (nonstimulated) nodes, however, remained morphologically normal throughout the response. Lymphocytes cytotoxic to the injected FeSV-transformed cells appeared in efferent lymph from the regional node within 5 days postinoculation and in lymph from distant nonstimulated nodes several days later. Cytotoxic lymphocytic cells had no killing effect against the corresponding non-transformed cells if the inoculum was autochthonous in origin; however, they did have such an effect when corresponding non-transformed cells were allogeneic. The cytotoxicity of the lymph cells varied according to the type of cells in the lymph. With the use of the growth inhibition assay, it was possible to demonstrate that lymph cell populations high in lymphoblasts killed all target cells in 24 hr, whereas populations of lymph cells comprised mainly of small lymphocytes took up to 2-3 days to kill the target cells. Complement-dependent antibody first appeared in lymph from the stimulated popliteal node at 8 and 12 days postinoculation in blood sera and lymph from distant nodes. (29 refs)

- 79-5838 Immunological Status of Patients Bearing Benign and Malignant Neoplasia. (Eng) Kudesia, M. (Dept. Pathology, Lady Hardinge Medical Coll., New Delhi, India); Malik, G. B. *Indian J Cancer* 15(3): 59-62; 1978.

The immunological status of 32 patients with malignant neoplasms (MN), 10 patients with benign neoplasms (BN), and 10 healthy controls was studied. Of the MN patients, 62.5% were tuberculin-negative, compared with only 10% in the BN and control groups. All MN patients with Stage I neoplasms were tuberculin-positive, whereas all with Stage IV neoplasms were negative. Blast transformation of lymphocytes was greatly reduced in the MN (24.92%) patients compared with the BN (51.00%) and control (52.17%)

subjects ($p = 0.0005$). The mean transformation index of the tuberculin-positive MN patients was 45.48%, compared with only 10.95% in the tuberculin-negative MN patients. Total serum proteins did not differ significantly between the MN and other subjects, but the concentration of serum globulin was significantly higher in the MN group than in the other two groups ($p = 0.0005$). (11 refs)

- 79-5839 Microspectrofluorometric Analysis of Surface Antigens of Murine Melanoma and Hamster Peritoneal Cell Hybrids: Comparisons of Species Antigenicity, Chromosome Number, and Tumorigenicity. (Eng) Erickson, K. L. (Dept. Human Anatomy, Sch. Medicine, Univ. California, Davis, CA 95616); Hu, F. *Oncology* 36(3): 101-104; 1979.

The surface antigenicity, karyotype, and tumorigenicity of somatic cell hybrids formed by the fusion of murine melanoma (PAZG) x Chinese hamster peritoneal cells (CH) were compared. One line, F57-(9), which arose from the hybridization of two CH cells and one PAZG cell, had slight (6%) CH chromosome loss but 80% PAZG chromosome loss after 10 mo in culture. These cells expressed CH antigens strongly and PAZG antigens weakly. In comparison, another hybrid, F57-(7), formed from one CH and one PAZG cell, lost 20% of its chromosomes after 10 mo in vitro. These cells had a stronger expression of PAZG antigens and a weaker expression of CH antigens than F57-(9). These findings indicate a direct relationship between chromosome number and antigenicity; tumorigenicity, however, does not appear to depend on the chromosome numbers of the parental cells. (25 refs)

- 79-5840 Pyoderma Gangrenosum and IgG Paraproteinemia. (Ger) Zabel, M. (Dermatologische Klinik und Poliklinik, Universitat Essen--GHS, Hufelandstrasse 55, D-4300 Essen, W. Germany); Brandle, I. *Med Klin* 74(10): 358-360; 1979.

The case report of a 68-yr-old patient with pyoderma gangrenosum and IgG paraproteinemia with kappa-type light chains is presented. The paraproteins that are observed in pyoderma gangrenosum without overt myeloma could represent early symptoms of plasmacytoma. (14 refs)

- 79-5841 The Distribution and Localization of Immunoglobulin in the Gastric Mucosa and Gastric Cancer. (Eng) Ohta, Y. (First Dept. Internal Medicine, Faculty Medicine, Univ. Tokyo, Hongo 7-3-1, Bunkyo-ku, Tokyo, Japan); Kino, I.; Kato, Y.; Aoyama, Y. *Acta Pathol Jpn* 29(4): 523-531; 1979.

The distribution and localization of immunoglobulin (Ig) in specimens of gastric mucosa, intestine, and gastric cancer were studied by immunofluorescence techniques. The gastric mucosa specimens were taken from stomachs with various degrees of chronic gastritis. Specimens of intestine were taken from cancer patients, but the tissue was removed far from the localized lesions, and it was histologically normal. IgA-producing cells predominated in the lamina propria of the stomach and in other regions of the gastrointestinal tract; in the stomach, however, the population density of all kinds of Ig-producing cells, especially those producing IgA, was more variable from case to case than that in the intestine. In metaplastic gastric mucosa, all IgA-, IgM-, and IgG-producing cells were reduced equally. In the intestine,

there was an even distribution of cells containing IgA and secretory component (SC: dimeric IgA bound with epithelial glycoprotein) in the glandular epithelium. In normal gastric mucosa, only a limited number of glands contained IgA and SC, mainly in the deep foveolar epithelium. However, almost all the glands in gastric metaplasia specimens contained IgA and SC. The distribution of IgA and SC was similar to that in the intestine. There were two interesting findings in the gastric cancer tissues: (1) 2/20 differentiated and 7/22 undifferentiated cancers were stained with anti-IgA and anti-SC antiserum. Thus, some gastric cancer cells retained the ability to produce SC and they took up IgA in their cytoplasm. In the differentiated cells, the specific fluorescence was present apically, whereas in the undifferentiated cells, it was distributed diffusely in the cytoplasm. (2) In one case of undifferentiated cancer, many IgG-producing inflammatory cells were observed in and around the cancer tissue. (21 refs)

- 79-5842 Hermans' Syndrome and Gastric Cancer. (Fre) Ram-pal, P. (Centre d'Hepato-gastro-enterologie, Avenue Reine Victoria 4, F-06000 Nice, France); Karsenty, C.; Prieur, J.; Vedel, J. P.; Delmont, J. *Acta Gastroenterol Belg* 42(3/4): 150-158; 1979.

A 64-yr-old woman developed a gastric adenocarcinoma as the last manifestation of late-onset immunoglobulin deficiency associated with nodular lymphoid hyperplasia of the ileum (Hermans' syndrome). The patient was admitted to the hospital in January 1973 with chronic diarrhea without fever or vomiting. There was no abdominal or arthritic pain. Immune studies showed very low levels of IgG and almost no IgM and IgA. Delayed hypersensitivity reactions to dinitrochlorobenzene and tuberculin were negative. The percentages of T and B lymphocytes were normal, but lymphoblast transformation tests were negative. The diarrhea failed to respond to medical treatment, and arthritic pain appeared in October 1973. A cancer of the antrum of the stomach was observed upon barium transit x-ray and endoscopy. Surgery in December 1973 revealed localized gastric cancer. Literature reports on gastrointestinal cancer in immune-deficient patients are briefly reviewed. (29 refs)

- 79-5843 The Effect of BCG Immunotherapy on the Kinetic Parameters and Growth Curves of Five Transplantable Colon Carcinoma Lines Chemically Induced in the Rat. (Fre) Martin, M. S. (Laboratoire d'Immunologie, Faculte de Medecine 7, Bd Jeanne-d'Arc, F 21033 Dijon, France); Martin, F.; Justrabo, E.; Michel, M. F.; Lagneau, A. *Gastroenterol Clin Biol* 3(3): 247-253; 1979.

The growth effects of two intratumoral injections of BCG were evaluated in five transplantable colon carcinoma lines induced by 1,2-dimethylhydrazine in BD-IX rats. Tumor fragments weighing 45-90 mg were implanted in the anterior of the rat thorax. As soon as the transplanted tumor measured 0.5 cm, the rats were inoculated intratumorally with BCG (2 0.5-ml doses of a 9-g/liter NaCl soln); control rats were inoculated intratumorally with NaCl. Of the total 165 grafts, 106 were successful. Several tumor growth parameters were measured and compared in the 51 rats inoculated with BCG and the 55 controls: length of survival, tumor volume, and metastases in animals with progressively growing tumors, doubling time, time required for the tumor to obtain a volume of 1 cm³, and the exponential growth curves following the Gompertz model. Although there were significant differences in the growth parameters among the five cell lines, BCG did not significantly alter tumor growth. (15 refs)

- 79-5844 Lymphocytes, Neutrophils and Serum Immunoglobulins in Patients with Precancerous States of the Larynx. (Eng) Gieriek, T. (Dept. Laryngology, Silesian Acad. Medicine, Francuska Str. 20/24, Katowice, Poland); Lisiewicz, J.; Astaldi, G.; Pilch, J. *Laryngoscope* 89(7, part 1): 1145-1150; 1979.

The lymphocyte and neutrophil cytochemistry and serum immunoglobulin levels were evaluated in 24 men aged 32 to 58 yr with precancerous states of the larynx, ie, leukoplakia, papillomas, and pachydermia. The peripheral blood lymphocytes were cytochemically stained for N-acetyl- β -glucosaminidase (AGA), β -glucuronidase (GU), acid phosphatase, and glycogen and the neutrophils were stained for alkaline phosphatase, myeloperoxidase, and lipids. The results were expressed in terms of absolute counts of positive cells and of the activity index score. IgG, IgA, and IgM levels were also determined. The results were compared with those in 20 healthy men aged 20-30 yr. The patients exhibited elevated numbers of AGA- and GU-positive lymphocytes. A characteristic feature was an increase in the absolute counts of lymphocytes with diffuse and granular-diffuse types of cytochemical reactions for all enzymes studied. The number of cells with the granular type of reaction (intact enzyme-positive lysosomes) was significantly reduced. These cytochemical alterations were accompanied by a significant increase in the serum IgA level. These results are discussed with reference to the response of the lymphoid system to tissues of precancerous lesions of the larynx. With respect to the neutrophils, the patients exhibited a significant intracellular decrease in GU activity and a decrease in lipid levels, as well as elevated alkaline phosphatase activity. The GU deficiency may be significant in the diminished cytotoxic response of the neutrophils against the tumor and precancerous lesion cells. (10 refs)

- 79-5845 Evaluation of the PHA Skin Test in Patients with Lung Cancer, Pulmonary Tuberculosis, and Leprosy. (Jpn) Kado, M. (Second Dept. Medicine, Chest Disease Res. Inst., Kyoto Univ., Kyoto, Japan); Kitaichi, M.; Matsui, Y.; Izumi, T.; Oshima, S.; Asamoto, H.; Motoaki, O. *Bull Chest Dis Res Inst Kyoto Univ* 12(1/2): 28-35; 1979.

The relationship between the immunological response of lung cancer patients to phytohemagglutinin (PHA) or purified protein derivative (PPD) and the types and stages of the disease was studied. Nine controls, 27 pulmonary tuberculosis patients, 14 leprosy patients, and 45 primary lung cancer patients (13 with squamous cell carcinoma, 17 with adenocarcinoma, 6 with small cell anaplastic carcinoma, and 9 with large cell anaplastic carcinoma; 9 Stage I, 5 Stage II, 21 Stage III, 10 Stage IV) were studied. Patients were inoculated sc with 5 μ g PHA or id with 0.05 μ g PPD in 0.1 ml saline and checked 24 or 48 hr later. In the PHA test, the av comparative diameter of the erythemas of the controls and the tuberculosis, lung cancer, and leprosy patients was 38.1, 31.2, 28.8, and 13.8 mm, respectively. The erythema diameter was 30.8, 32.4, 29.1, and 24.7 mm for the Stage I, II, III, and IV lung cancer patients, respectively. Low reactivity rates were generally seen in patients with small cell anaplastic carcinoma. The overall PPD reaction in the lung cancer patients was 62.8% of normal. A positive correlation between the PPD and the PHA reactions was observed in 27/43 lung cancer patients tested. No changes in the levels of RBC, WBC, glutamic pyruvic transaminase, lactate dehydrogenase, blood urea nitrogen, and lymphocytes were seen before or after the PHA test. There was a decreased immunological reaction in the later stages of lung cancer, as judged by the immunological responses of the hosts to the PHA test. (16 refs)

79-5846 Neoplasma and Kidney Transplants. Study at the Kidney Transplantation Unit of the Maisonneuve-Rosemont Hospital. (Fre) Archambault-Couture, L. (Departement de Medecine, Hopital Maisonneuve-Rosemont, Universite de Montreal, Quebec, Canada); Beaudry, C.; Legresley, L. P.; Laplante, L. *Union Med Can* 108(6): 681-684; 1979.

Three kidney transplant patients who developed a reticulosarcoma of the cerebellum, a hypernephroma, and a Wilms' tumor, respectively, are described. These three neoplasms were the only ones observed among a series of 179 kidney transplants performed in 162 patients during 1968-1978. The Wilms' tumor, which occurred in a 22-yr-old woman, is believed to be the first one to develop after a kidney transplant. (8 refs)

79-5847 Loss of Strain Specificity of the TA3-St Subline: Evidence for the Role of Epiglycanin in Mouse Allogeneic Tumor Growth. (Eng) Cooper, A. G. (Dept. Pathology, Tufts Univ. Sch. Medicine, Boston, MA 02111); Codington, J. F.; Miller, D. K.; Brown, M. C. *J Natl Cancer Inst* 63(1): 163-169; 1979.

The in vivo conversion of the standard strain-specific ascites murine mammary adenocarcinoma subline TA3-St to a new subline, TA3-MM, is reported. While TA3-St is neither allogeneically transplantable nor epiglycanin-bearing, the new subline did bear epiglycanin and grew in allogeneic mice in this study. The simultaneous acquisition of these two properties strongly suggests the role of epiglycanin in allogeneic tumor growth. (21 refs)

79-5848 Isolation and Partial Characterization of an Epiglycanin-like Glycoprotein from a New Non-Strain-specific Subline of TA3 Murine Mammary Adenocarcinoma. (Eng) Codington, J. F. (Lab. Carbohydrate Res., Massachusetts General Hosp., Boston, MA 02114); Cooper, A. G.; Miller, D. K.; Slayter, H. S.; Brown, M. C.; Silber, C.; Jeanloz, R. W. *J Natl Cancer Inst* 63(1): 153-161; 1979.

The detection, isolation, and partial characterization of an epiglycanin (EGC)-like glycoprotein (gp) from a new non-strain-specific ascites subline of the TA3 mammary adenocarcinoma TA3-MM are described. The subline, which arose in vivo from the strain-specific TA3-St subline during an acute respiratory illness of the syngeneic A/HeHa hosts, possessed at its surface a gp not found on the parent TA3-St cell. This gp, termed TA3-MM EGC, was characterized by a high mol wt (500,000), by potent inhibition of hemagglutination by the *Vicia graminea* lectin, and by carbohydrate and amino acid compositions nearly identical to those of the EGC gp present on the surface of the allotransplantable TA3-Ha ascites cell. Under the electron microscope, TA3-MM EGC present appeared as long extended rods with widths [2.5 nanometers (nm)] and lengths (450-500 nm) similar to those of TA3-Ha EGC. Incubation of each of two sublines of the TA3-MM ascites cell, TA3-MM/1 and TA3-MM/2, with modified trypsin followed by column chromatography produced approx 1.0- and 0.2-fold as much EGC-like material, respectively, as was obtained from the TA3-Ha ascites cell. Continuous growth of the TA3-MM cell in suspension culture resulted in an almost complete disappearance of EGC in a manner demonstrated earlier for the TA3-Ha cell grown under similar conditions. Allotransplantability in the TA3-MM cell may be due, at least in part, to the masking of histocompatibility antigens by EGC-like molecules. (30 refs)

79-5849 A Study of Host Defence Reaction of Breast Carcinoma and its Correlation with Generalised Delayed Hypersensitivity. (Eng) Nagar, R. (Dept. Pathology and Surgery, Lady Hardinge Medical Coll. and Hosp., New Delhi, India); Maheshwari, H. B.; Mukerjee, P.; Mittal, M. M. *Indian J Cancer* 15(3): 63-68; 1978.

Twenty-six patients with breast carcinoma (BC), 20 patients with benign breast neoplasms (BBN), and 20 normal, age-matched controls were studied for delayed hypersensitivity reactions and host defense reactions. In the controls and BBN group, a positive reaction to the tuberculin sensitivity test was achieved with 5 or 10 units of tuberculin. Fifteen of the BC patients responded to 5 units, 7 responded to 10 units, 2 responded to 100 units, and 2 did not respond. Two peaks of induration were observed in 75% of the normal controls after id injections of 2.5 million lymphocytes (NLT test). No reaction was observed within 10 days in 8/26 BC patients, only one peak was observed in 5 patients, two normal peaks were observed in 12 patients, and two abnormal peaks were observed in 1 patient. Contact sensitivity to dinitrochlorobenzene (DNCB) was induced in 20 BC, 20 BBN, and 15 control cases. A poorer response of the lymphoreticuloendothelial (LR-E) cells in and around the tumor and draining lymph nodes was observed in patients with advanced BC. The maximum depression of delayed hypersensitivity was observed in patients with Stage IV malignancy. The status of delayed hypersensitivity based on the tuberculin, DNCB, and NLT tests correlated with the LR-E reaction. (20 refs)

79-5850 Assessment of Cell Immunity in Precancerous Stages and in Carcinoma of the Cervix. (Ita) Bolis, P. F. (Cattedra di Patologia Ostetrica e Ginecologica, Universita degli Studi di Pavia, Pavia, Italy); Polatti, F.; Zara, C. *Minerva Ginecol* 31(6): 445-447; 1979.

Erythrocyte (E)-rosette formation was studied in 19 patients with moderate cervical dysplasia, 12 with carcinoma in situ (CIS) of the cervix, and 16 with invasive cervical carcinoma. E-rosette formation in the dysplasia and CIS patients was comparable to that observed in controls (45.5%, 51.2%, and 50.4%, respectively), but it was reduced significantly in patients with invasive carcinoma (31.9%). It is suggested that the neoplasia is initially controlled by the cell-mediated immunity of the host and that it becomes invasive when this immunity proves insufficient. (11 refs)

PATHOGENESIS

- 79-5851 Measurement of Chromosomal Breakage in Cultured Cells by the Micronucleus Technique. (Eng) Heddle, J. A. (Dept. Biology, York Univ., Downsview, Toronto, Ontario M3J 1P3, Canada); Benz, R. D.; Countryman, P. I. In: *Mutagen-induced Chromosome Damage in Man. Proceedings of a Symposium held in Edinburgh, Scotland, July 7-8, 1977*. Medical Research Council (Edinburgh, Scotland): 355 pp.; 191-196; 1978.

A series of experiments are reported in which chromosomal breakage in cultured cells was measured by the micronucleus technique. One of the consequences of chromosomal breakage is the production of micronuclei, and the number of micronuclei present in cells depends upon the extent of chromosomal breakage as well as other factors. The main advantage of measuring the micronuclei rather than the chromosomal aberrations directly is that the sampling time is greatly reduced since the technique is faster and requires less expertise. The main disadvantage is that even though the aberration frequency is constant, the frequency of micronuclei varies with the rate of cell division and the proportion of cells that divide. A miniature blood culture is set up in a microtube. The standard sampling time is 96 hr after the culture is begun. One slide is made per culture, and 500 cells from it are scored. The micronuclei are scored, even if three or more occur in the same cell, provided that there is a distinct main nucleus which is rounded rather than deeply lobulated. Data are presented from use of the test with normal lymphocyte cultures exposed to x-rays (400 R); with cultures from Down's syndrome donors and normal diploid donors irradiated at varying doses; with normal lymphocytes exposed to 400 R x-rays given in two 200 R fractions; with lymphocytes from control, Fanconi's anemia and Bloom's syndrome donors and their heterozygotes; with lymphocytes from Fanconi's anemia and control patients after mitomycin C was added at varying doses to the culture; and with ataxia telangiectasia and control fibroblast lines after anoxic γ -irradiation. Provided that the limitations of this assay are recognized, it can be a useful measure of chromosome breakage. (18 refs)

- 79-5852 Human Chromosomes Which Affect Tumorigenicity in Hybrids of Diploid Human with Heteroploid Human or Rodent Cells. (Eng) Klinger, H. P. (Dept. Genetics, Albert Einstein Coll. Medicine, Bronx, NY); Baim, A. S.; Eun, C. K.; Shows, T. B.; Ruddle, F. H. *Cytogenet Cell Genet* 22(1-6): 245-249; 1978.

A study was conducted to determine if chromosomes (CS's) of human diploid (HD) cells can influence the tumorigenicity, in nude mice, of heteroploid human or rodent cells when introduced into the latter by cell fusion. Three series of hybrids between normal HD and heteroploid HPRT-deficient cells of human (D98AH2), Chinese hamster ovary (K627), and mouse (A9) origin were made, and a set of hybrids was selected from each series so that nearly all human CS's were represented in each set. Intraspecific hybrids that retained most of the CS's of the nontumorigenic diploid parent were also nontumorigenic. Preliminary results from the interspecific HD x rodent crosses showed that no human CS in single copy appears to be able to greatly affect tumorigenicity, since nearly all human CS's were represented at least once in cells of the

resulting tumors. This was also true for about 130 combinations of different CS's taken two at a time. However, many hybrids, particularly those with many human CS's, required higher cell inocula or longer periods of time to form tumors than heteroploid parental lines. CS's 8, 9, 11, 13, and 17 conveyed characteristics to cells that reduced their tumorigenic potential. However, the data are not extensive enough to rule out the possibility that other combinations of human CS's may have similar effects. In the HD x D98AH2 and HD x K627 series, the anchorage-independent and tumorigenic phenotypes did not fully correlate, since some hybrids able to grow in semisolid medium were not able to form tumors. However, a quantitative relationship may exist between these phenotypes, since most of the nontumorigenic hybrids had low plating efficiencies and grew slowly in semisolid medium, and the tumorigenic hybrids and the cells of their tumors generally grew quickly and plated at much higher efficiencies in this medium. The data are not compatible with the view that extrachromosomal elements intervene in the suppression of tumorigenicity, although this possibility is difficult to rule out. (8 refs)

- 79-5853 A Possible Association of Pernicious Anemia with Neoplasia. (Eng) Arvanitakis, C. (Dept. Medicine, Univ. Kansas Medical Center, Rainbow Blvd. at 39th St., Kansas City, KS 66103); Holmes, F. F.; Hearne, E. *Oncology* 36(3): 127-129; 1979.

To obtain further information on the incidence of neoplasms in pernicious anemia (PA), 39 PA patients (20 women, 19 men) seen at one institution over a 20-yr period were studied. Seven of the patients developed nine different neoplasms 3-20 yr after the diagnosis of PA. These primary neoplasms originated from the lymph nodes, larynx, colon, stomach, kidney, meninges, maxillary sinus, and eighth nerve. Treatment with vitamin B₁₂ did not influence tumor development. Statistical analysis showed that the observed incidence of nine neoplasms in this group was significantly higher than the expected 3.3 cases during the aggregate follow-up period ($p = 0.002$). Although a higher incidence of neoplasms in patients with other underlying diseases does not necessarily indicate an association, a high degree of suspicion for neoplastic disease is justifiable in PA patients. - 79-5854 Familial Hodgkin's Disease: Case Report and Literature Review. (Ger) Hofer, H. O. (Medizinische Universitätsklinik Göttingen, Robert-Koch-Strasse 40, D-3400 Göttingen, W. Germany); Nagel-Studer, E.; Nagel, G. A. *Onkologie* 2(3): 113-118; 1979.

Malignant lymphoma [3 cases of Hodgkin's disease (HD), 1 case of reticulum cell sarcoma] developed in 4/5 sisters; two cases were diagnosed in 1962-1964 and two in 1971. The sisters who developed malignancies had similar immune response patterns, and these differed from the pattern of the healthy sister. This observation, plus a review of the literature on familial HD, are consistent with the view that an external agent plus inherited susceptibility are involved in HD. (85 refs)

79-5855 Chronic Myelomonocytic Leukemia Associated with Hereditary Pyruvate Kinase Deficiency and Multiple Acquired Erythrocyte Abnormalities. (Eng) Vives-Corrons, J. L. (Postgraduate Sch. Hematology 'Farreras Valenti', Hospital Clinico y Provincial, Univ. Barcelona, c/ Casonova, 143 Barcelona, Spain); Florensa, L.; Muncunill, J.; Nomdedeu, B.; Rozman, C. *Acta Haematol (Basel)* 61(3): 168-174; 1979.

A congenital RBC pyruvate kinase (PK) deficiency was found in a 72-yr-old woman with chronic myelomonocytic leukemia (CMML). The PK deficiency was associated with an increase in the RBC activity of hexokinase, 6-phosphogluconate dehydrogenase, and glutathione peroxidase and with a decrease in the activity of acetylcholinesterase, glutathione reductase, and glucosephosphate isomerase. The enzymatic abnormalities were accompanied by alterations in hemoglobin and in the i antigen content of the RBC membrane. In addition, bone marrow ultrastructural studies showed dyshemopoietic changes in all blood cell precursors and especially in erythroblasts. These findings confirm the close relationship between CMML and acquired dyserythropoietic syndromes, and they may help to clarify the nature of the rare association of hereditary PK deficiency with leukemia. (53 refs)

79-5856 Chronic Myelogenous Leukemia with Reticulum-Cell-Sarcoma-like Cell Proliferation. (Eng) Koide, O. (Dept. Pathology, Univ. Occupational and Environmental Health, Sch. Medicine, 1-1 Iseigaoka, Yahata, Nishi-ku, Kitakyushu 807, Japan); Watanabe, Y. *Acta Pathol Jpn* 29(4): 585-595; 1979.

A case of chronic myelogenous leukemia (CML) associated with a proliferation of atypical cells resembling those of reticulum cell sarcoma (RCS) is presented. The patient, a 41-yr-old man, presented with a short history of palpitation and general fatigue. Anemia, splenomegaly, and leukocytosis were discovered upon admission, and a diagnosis of CML was made. Approx 2.5 yr later, he was readmitted with acute crisis of CML, and he died soon thereafter. Histologic studies revealed the presence of several immature eosinophils intermingled with ordinary leukemic cells that had infiltrated the bone marrow, lymph nodes, spleen, liver, lungs, and testes. RCS-like cells either formed solitary nodular foci or they intermingled randomly with infiltrating leukemic cells. Charcot-Leyden crystals were seen in some areas where RCS-like cells proliferated. Eosinophilic granules were present in some of the RCS-like cells. They proved to be an immature form of specific granules of eosinophils, as evidenced by their staining properties and ultrastructural aspects. These results favor the view that the RCS-like cells are transformed leukemic cells of myelogenous origin. (25 refs)

79-5857 The Skin in Myelomonocytic Leukemia. (Ita) Carlesimo, O. A. (Clinica Dermatologica, Univ. Roma, Rome, Italy); Calvieri, S.; Chimenti, S.; Pala, S.; Bertana, C. *Chronica Dermatol* 9(6): 631-636; 1978.

A case of myelomonocytic leukemia with skin manifestations occurred in a 72-yr-old man. The patient presented with a 6-mo history of papular skin lesions that covered almost the entire body, particularly the trunk, face, and arms. No abnormalities were found on physical examination except a moderately enlarged liver. Blood tests revealed $3,200,000 \text{ RBC/mm}^3$, $3,000 \text{ WBC/mm}^3$ (70% lymphocytes, 18% blast cells), and an elevated IgG level. Tests for the Philadelphia chromosome were negative. Cytologically, large round cells with large, hyperchromic, centrally located nuclei

predominated. Occasionally, nucleoli were present. The cytoplasm was abundant and slightly basophilic. Histological examination of the skin lesions revealed essentially the same type of cell (large, round, monomorphic cells with large hyperchromic nuclei and an occasional nucleolus); however, the cytoplasm was eosinophilic. These cells were also prevalent in the bone marrow. Electron microscopic examination of ultrathin sections of the leukemic cells demonstrated numerous electron-dense granular vesicles in the cytoplasm. The patient was diagnosed as having myelomonocytic leukemia with skin infiltrations. (15 refs)

79-5858 The Hypophysis and Hemoblastoses. (Ger) Buchmann, E. (Pathologisches Institut der Ernst-Moritz-Arndt-Universität, Friedrich-Loeffler-Strasse 23e, DDR-22 Griefswald, E. Germany); Schwesinger, G. *Zentralbl Neurochir* 40(1): 35-42; 1979.

Among a series of autopsies of 165 patients with hemoblastoses, 38 cases of infiltration of the hypophysis were found. The highest incidence of hypophyseal infiltration was found among the lymphoblastic leukemias (3/9), followed by 18/62 cases of non-Hodgkin's lymphoma, 16/76 cases of myeloblastic leukemia, and 1/18 cases of Hodgkin's disease. (27 refs)

79-5859 Acute Nonlymphocytic Leukemia. Expression in Cells Restricted to Granulocytic and Monocytic Differentiation. (Eng) Fialkow, P. J. (Medical Service, Veterans Admin. Medical Center, 4435 Beacon Ave. S., Seattle, WA 98108); Singer, J. W.; Adamson, J. W.; Berkow, R. L.; Friedman, J. M.; Jacobson, R. J.; Moehr, J. W. *N Engl J Med* 301(1): 1-5; 1979.

Two patients (a 29-yr-old woman and a 2.5-yr-old girl) with acute nonlymphocytic leukemia who were heterozygous for the X-chromosome-linked enzyme glucose-6-phosphate dehydrogenase were studied to determine the number and type of cells in which the disease arises. Both type A and B isoenzymes were found in normal tissues, but the myeloblasts showed only one enzyme type, indicating that at the time of the study, the disease had a clonal origin. The observation in one patient that erythroid cells did not arise from this clone contrasts with conclusions reached in patients previously studied with chromosome markers. The results suggest that in this patient, the leukemic clone suppressed the expression of normal granulopoiesis but did not inhibit erythroid differentiation from normal progenitors. They suggest also that the disease is heterogeneous. In some patients, the disease is expressed in cells with differentiation restricted to the granulocyte-macrophage pathway; in others, it involves stem cells that also differentiate into RBC. This heterogeneity may reflect differences in causation and could have prognostic importance. (38 refs)

79-5860 Lymphomatoid Papulosis: A Recently Discovered Anatomical-Clinical Entity. (Ita) Eusebi, V. (Istituto di Anatomia e Istologia Patologia, Università di Bologna, Bologna, Italy); Bondi, A.; Bisighini, G.; Moroni, P. *Chronica Dermatol* 9(6): 651-660; 1978.

Three cases of lymphomatoid papulosis are reported. The differential diagnosis of this condition from diseases such as pityriasis lichenoides et varioliformis acuta, actinic reticuloid, mycosis

fungoides, and cutaneous lymphoma is considered, along with its histogenesis. (18 refs)

- 79-5861 Cutaneous Malignant Lymphoma in a Patient with Sarcoidosis. (Ita) Farris, A. (Divisione Dermatologica, Ospedali Civili di Genova, Genoa, Italy); Bacigalupo, A. *Chronica Dermatol* 9(6): 731-736; 1978.

A case of cutaneous malignant lymphoma developed in a 22-yr-old woman with sarcoidosis. The possible lymphomatous evolution of sarcoidosis is discussed. (30 refs)

- 79-5862 Pure Red Cell Aplasia and Lymphoma. (Eng) Carlsson, H. W. (Div. Hematology-Oncology, Scripps Clinic and Res. Foundation, 10666 N. Torrey Pines Road, La Jolla, CA 92037); Saab, G. A.; Tavassoli, M. *JAMA* 242(1): 67-68; 1979.

The case report of a 27-yr-old woman in whom pure red cell aplasia (PRCA) occurred several months after the diagnosis of poorly differentiated lymphocytic lymphoma is presented. PRCA was associated with lymphomatous infiltration of the bone marrow. Eighteen days after institution of therapy with doxorubicin hydrochloride-cyclophosphamide- vincristine-prednisone, clinical remission was achieved, and it was associated with the disappearance of malignant cells from the bone marrow and with the reappearance of RBC precursors. (6 refs)

- 79-5863 Primary Malignant Lymphoma of the CNS and Polyneuropathy in a Patient with Necrotizing Vasculitis Treated with Immunosuppression. (Eng) Jellinger, K. (Ludwig-Boltzmann-Institut für Klin. Neurobiologie, Krankenhaus Lanz, Wolkersbergenstrasse 1, A-1130 Vienna, Austria); Kothbauer, P.; Weiss, R.; Sunder-Plassmann, E. *J Neurol* 220(4): 259-268; 1979.

The development of peripheral neuropathy and a rapidly progressing cerebral disorder suggestive of a basal meningeal process was seen in a 58-yr-old woman who had undergone treatment with corticosteroids and azathioprine for generalized necrotizing vasculitis. Cerebrospinal fluid cytology suggested malignant lymphoma with meningeal involvement, and immunological studies showed an increase in null lymphocytes in the peripheral blood. Autopsy disclosed a primary malignant lymphoma of the CNS with the histologic appearance of a multilocal immunoblastoma showing almost ubiquitous meningeal involvement. Clinical and postmortem examinations failed to demonstrate any systemic extraneural lymphoproliferative disorder. There was peripheral polyneuropathy of the axonal type with denervation atrophy of the skeletal muscle, but without lymphomatous involvement of the neuromuscular system. The pathogenic background of peripheral polyneuropathy is unknown. (44 refs)

- 79-5864 Manifestation of a Highly Malignant Lymphoma in the Terminal Stage of Mycosis Fungoides. Enzyme Cytochemical and Immunocytological Investigations. (Ger) Buchner, S. (Dermatologische Klinik und Poliklinik, Universität Basel, Petersgraben 4, CH-4031 Basel, Switzerland); Rufli, T. *Dermatologica* 159(2): 125-131; 1979.

After a 24-yr history of mycosis fungoides, a 50-yr-old man rapidly developed a generalized highly malignant lymphoma. The diagnosis was confirmed by cytomorphological and enzyme cytochemical methods (demonstration of hydrolytic enzymes in cryostat sections, cutaneous smears, and cell suspensions extracted from skin lesions), as well as by immunocytological methods (differentiation of lymphocyte subpopulations). In the tumor stage of mycosis fungoides, a polymorphous infiltrate composed of lymphocytoid and monocytoid cells prevailed, but a proliferation of lymphoblastic cells was present in the terminal stage. These cells no longer showed the properties of mature lymphocytes, and they also differed in their enzyme-cytochemical pattern. (19 refs)

- 79-5865 Lymphatic Metastasis of Tumour; Persistent Transport of Cells. (Eng) Carr, J. (Dept. Physiology, Univ. Saskatchewan, Saskatoon, Saskatchewan, S7N 0W0, Canada); Carr, I.; Dreher, B.; Franks, C. R. *Experientia* 35(6): 825-827; 1979.

A model of lymphatic metastasis established by injecting Walker rat carcinoma cells into the footpad of outbred albino rats was used to study the output of tumor cells from the footpad. The presence of metastasis was established by histological examination of step paraffin sections of the ipsilateral popliteal lymph node. Injection of 20 million tumor cells of >90% viability into adult rats produced metastasis in >90% of the animals. The lymphatic efferent from the footpad was cannulated in a group of rats with advanced neoplasm. All 12 tumor bearing animals were cannulated successfully 7-9 days after transplantation. Tumor cells were seen in the lymph in all samples taken. All animals had metastasis in the popliteal lymph node. It was shown that the output of tumor cells via a single lymphatic efferent was continuous over periods up to 90 min and ranged from 10^2 to 10^5 cells/min. Broadly, the number of tumor cells leaving the footpad by a single lymphatic was directly related to the size of the primary tumor. (6 refs)

- 79-5866 Leukemia Occurring in Treated Hodgkin's Disease: Two Neoplasms or One? (Eng) Sheibani, K. (Div. Lab. Medicine, Cleveland Clinic, Cleveland, OH); Tubbs, R. R.; Savage, R. A.; Valenzuela, R.; Sebek, B. A.; Hewlett, J. S. *Cleve Clin Q* 46(2): 39-47; 1979.

A 46-yr-old man developed a second, morphologically distinct neoplasm approx 2 yr after the onset of nodular sclerosing Hodgkin's disease, Stage I. The patient had received 4,000 rads to the right and left supraclavicular lymph node areas at the time of diagnosis and, 8 mo later, he was started on MOPP (nitrogen mustard, vincristine, prednisone, procarbazine) chemotherapy. At the start of chemotherapy, a posterior iliac crest bone marrow (BM) biopsy specimen contained small foci of undifferentiated cells suggestive of acute monocytic leukemia. About 10 mo later, BM aspirate and a BM biopsy revealed complete replacement with primitive cells having pleomorphic folded nuclei suggestive of histiocytic lymphoma or monocytic leukemia. The patient died 1 mo later. At no time during the course of his illness were malignant cells identified in the peripheral blood. At autopsy, pleural nodules were found. The infiltrate in these nodules and in the BM consisted of large pleomorphic mononuclear cells with vesicular nuclei and prominent basophilic nucleoli. Binucleate and multinucleate variants were also found, but typical Reed-Sternberg cells (diagnostic of the original neoplasm) were not identified. The results of comparative studies of the two neoplasms showed cytochemical, cytologic, and immunologic differences. The reac-

tivity of cells from the two neoplasms toward sheep RBC (SRBC) and SRBC coated with antibody and complement was also different. It is suggested that the evolution of treated Hodgkin's disease may involve a change in the cytochemical and immunologic characteristics of the neoplasm, possibly reflecting a selective effect of treatment of varying cell types within the original neoplasm, and that the second neoplasm represented an overgrowth of one component of a single neoplasm rather than a new malignancy. (8 refs)

- 79-5867 Possible HLA Role in a Family with Hodgkin's Disease. (Eng) Nunez-Roldan, A. (Histocompatibility Lab., Dept. Biochemistry, Univ. Hosp., Seville, Spain); Martinez-Guibelalde, F.; Gomez-Garcia, P.; Gomez-Pereira, C.; Nunez-Ollero, G.; Torres-Gomez, A. *Tissue Antigens Histocompat Immunogenet* 13(5): 377-378; 1979.

Three siblings from a family of seven children were found to have Hodgkin's disease (mixed cellularity type) within 1 mo. Histocompatibility locus antigen (HLA) typing revealed that all three siblings had inherited the same haplotype from each parent; ie, A1-B5 from the mother and A26-B18 from the father. The coincidence of Hodgkin's disease in the only siblings who possessed the same HLA genotype suggests an association of the major histocompatibility complex genes and susceptibility to the disease within this family. The development of the disease in all three siblings within 1 mo suggests that a virus might also be involved. (4 refs)

- 79-5868 The Coexistence of Parathyroid Adenoma and Thyroid Carcinoma. (Eng) Calcaterra, T. C. (Div. Head and Neck Surgery, UCLA Sch. Medicine, Los Angeles, CA 90024); Paglia, D. *Laryngoscope* 89(7, part 1): 1166-1169; 1979.

The possible significance of the relationship between parathyroid adenoma and nonmedullary thyroid carcinoma was studied. Among a series of 144 patients with parathyroid adenoma, 11 had concurrent thyroid carcinoma. Although these two tumors are similar to other multiple endocrine tumor syndromes, they have no common embryonic cell origin. The most likely explanation for this apparent relationship is the specific oncogenic effect of hypercalcemia on the thyroid gland. (9 refs)

- 79-5869 Report of a Case of Recklinghausen's Disease Associated with a Pituitary Adenoma. (Ita) Barberis, M. (Istituto di Anatomia patologica, Ospedale Maggiore "Ca' Granda" di Milano-Niguarda, Milan, Italy); Gambacorta, M.; Versari, P.; Filizzolo, F. *Pathologica* 71(1012): 265-272; 1979.

A case of cutaneous and visceral von Recklinghausen's disease associated with an acidophilic pituitary adenoma is reported. (9 refs)

- 79-5870 Familial Endocrine Adenomatosis. (Ger) Muhlenstedt, D. (Institut für Humangenetik, Vesaliusweg 12/14, D-4400 Münster, W. Germany); Schneider, H. P.; Lenz, W. *Med Klin* 74(14): 520-523; 1979.

The combination of pituitary and thyroid gland adenomatosis oc-

curred in four family members of two generations. The finding of a dominant inheritance is discussed with special reference to multiple endocrine adenomatosis (Wermer's syndrome). The endocrine status of the patients, including the results of dynamic function tests, is presented. In cases of monoglandular adenomatosis, clinical attention should be directed not only to the anterior pituitary and thyroid glands, but also to the possible simultaneous occurrence of tumors of the parathyroid gland or the pancreas. (27 refs)

- 79-5871 Metastases in the Hypophysis. (Ger) Grabow, D. (Pathologisches Institut der Ernst-Moritz-Arndt-Universität, Friedrich-Loeffler-Strasse 23e, DDR-22 Griefswald, E. Germany); Schwesinger, G. *Zentralbl Neurochir* 40(1): 29-34; 1979.

Among 1,521 autopsies of patients with extracranial malignancies, 64 cases of metastases to the hypophysis were found. The primary cancer was breast carcinoma in 21.4% of the cases, malignant melanoma in 19.0%, and sympathoblastoma in 12.5%. Generalized metastases were found in 59/64 patients, indicating that hypophyseal involvement occurs during advanced disease stages. (15 refs)

- 79-5872 Coexisting Benign Mixed Tumor and Mucoepidermoid Carcinoma of the Parotid Gland. (Eng) Pontilena, N. (Dept. Otolaryngology, Columbia-Presbyterian Medical Center, New York, NY); Rankow, R. M. *Ann Otol Rhinol Laryngol* 88(3, part 1): 327-330; 1979.

Multiple unilateral parotid gland tumors are very rare. A review of the literature shows only seven cases of coexisting unilateral parotid tumors. The eighth case, a benign mixed tumor and a mucoepidermoid carcinoma of the right parotid gland, is described. The patient was a 45-yr-old woman who noticed a swelling in the right parotid region approx 10 yr prior to her admission. She denied pain in the mass, facial asymmetry, or any sudden increase in the size of the mass. Permanent sectioning of the parotid specimen revealed two discrete tumors. One tumor demonstrated one large and several smaller cystic spaces filled with a basophilic myxoid material and lined by one or two rows of cuboidal or low columnar cells. This was a benign mixed tumor. The second tumor was a low-grade mucoepidermoid carcinoma consisting of solid sheets of squamous epithelial cells and glandular structures lined by tall columnar cells and occasional goblet cells. These were separated by dense fibrous connective tissue. This the the first case of multiple unilateral parotid tumors to show such a tumor combination. (15 refs)

- 79-5873 Case Report. Turcot's Syndrome and Its Mode of Inheritance. (Eng) Itoh, H. (Dept. Surgery I, Kyushu Univ. Faculty Medicine, Maedashi 3-1-1, Fukuoka, Japan 812); Ohsato, K.; Yao, T.; Iida, M.; Watanabe, H. *Gut* 20(5): 414-419; 1979.

The occurrence of malignant cerebral neoplasms (grade 3 astrocytomas) in two sisters with Turcot's syndrome (TS) and colonic polyposis is reported. The parents of the patients were first cousins; neither had colonic polyps or neurological disorders. In two previously reported familial cases of TC, the disease occurred in both sexes but only among siblings. Neither colonic polyposis

nor brain tumors were found in the parents or other members of the families. In one of these two cases, the patient's parents were third cousins. It is concluded that the mode of inheritance of TC is autosomal recessive and that this disorder is genetically distinct from the ordinary form of familial polyposis coli. The absence of an association between the two disorders is supported by differences in the number, size, and distribution of colonic polyps. (17 refs)

- 79-5874 Widespread Carcinomatous Infiltration of the Meninges. (Ger) Steinhausl, H. (Neurologische Abteilung, Wagner-Jauregg-Krankenhaus, Wagner-Jauregg-Weg 15, A-4020 Linz, Austria). *Wien Med Wochenschr* 129(12): 341-343; 1979.

The case report of a 38-yr-old woman with meningeal carcinomatosis is presented, and the clinical picture of this condition is discussed. Examination of the cerebrospinal fluid is the most useful procedure for diagnosing of meningeal carcinomatosis. The clinical picture is very similar to that of meningitis tuberculosa. (5 refs)

- 79-5875 Recurrent Orbital and Metastatic Melanoma in a Patient Undergoing Previous Glaucoma Surgery. (Eng) Singer, P. R. (Dept. Ophthalmology, Washington Univ. Sch. Medicine, 660 S. Euclid Ave., St. Louis, MO 63110); Krupin, T.; Smith, M. E.; Becker, B. *Am J Ophthalmol* 87(6): 766-768; 1979.

A 61-yr-old woman with unilateral acute angle-closure glaucoma underwent a Scheie filtering operation. After a 2-wk interval, a large choroidal and ciliary body melanoma was found in the glaucomatous eye. There was no evidence of metastatic disease, and the eye was enucleated. Histopathologic sections did not show extrascleral extension. After 2.5 yr, the patient developed local orbital recurrence of the melanoma and fatal metastatic disease. A possible causal relationship between the filtering surgery and the local and systemic recurrence of the tumor is hypothesized. (7 refs)

- 79-5876 Two Cases of Intraepidermal Squamous Cell Carcinoma (Bowen's Tumor). (Rum) Jalobceastii, L. (No affiliation given.); Buiuc, S.; Beschea, G. *Rev Chir [Oftalmol]* 23(1): 77-79; 1979.

Two clinical cases of Bowen's tumor (intraepidermal squamous cell carcinoma) developed on the limbus and extended to the cornea of two men aged 37 and 64 yr. Examination of the lesions revealed thickening of the epithelium, mitosis in all epithelial layers, dyskeratosis, and an intact basement membrane. (10 refs)

- 79-5877 Malignant Melanoma of the Choroid in Melanosis Oculi. (Ger) Hubel, K. (Univ.-Augenlinik, Auenbruggerplatz 4, A-8036 Graz, Austria); Hanselmayer, H. *Klin Monatsbl Augenheilkd* 174(3): 404-407; 1979.

A malignant melanoma of the choroid developed in a 33-yr-old woman with melanosis oculi. The incidence of malignant melanoma is much higher in patients with melanosis oculi than in

normal subjects. Regular (every 1-2 yr) microscopic examinations should be made of such patients in order to detect the development of a melanoma at an early stage. (13 refs)

- 79-5878 The Small Congenital Nevocytic Nevus and Malignant Melanoma (Letter to Editor). (Eng) Kirschenbaum, M. B. (6450 N. California Ave., Chicago, IL 60645). *JAMA* 242(1): 26; 1979.

Although malignant melanoma has been reported to occur in the large "bathing trunk nevus" in up to 20% of patients, there is little evidence that malignant transformation occurs in small, congenital, nevocytic nevi. (no refs)

- 79-5879 Correlation Between Differentiation and Malignancy in Human Malignant Melanocytes In Vivo and In Vitro. (Fre) Foa, C. (Unité 119 de l'Inserm, 27 Boulevard Leirou, F 13009 Marseille, France). *Bull Cancer (Paris)* 66(3): 287-292; 1979.

Cell lines established from human primary malignant melanomas were studied in order to correlate their ultrastructural and biochemical characteristics and their malignant potential. Variability in the size of the cell and nucleus, the type and number of melanosomes, the presence of concentric bodies and vacuoles, etc, was accompanied by variability in the location of dopaoxidase (Golgi bodies, endoplasmic reticulum, small vesicles), level of 5-S-cysteinyl-dopa, and chromosome pattern. The malignant potential of the cultured cell lines was tested by heterotransplantation into hamster cheek pouches and nude mice. Both the in vivo and in vitro studies showed that a relationship between melanization and malignant potential cannot be established. Highly pigmented human melanoma cell lines were more likely to give rise to tumors in experimental animals; however, achromic cell lines were also heterotransplantable, and one highly pigmented cell line was not heterotransplantable. (80 refs)

- 79-5880 Histological Classification of Primary Melanoma in Relation to Therapeutic Procedures and Prognosis. (Yug) Jakasa, V. (Sredisnji institut za tumore i slicne bolesti, Zagreb, Yugoslavia); Popovic, S.; Kosanovic, S.; Maricic, Z.; Nola, P. *Lijec Vjesn* 101(2): 70-72; 1979.

Excluding rare melanomas originating in a blue nevus, primary cutaneous melanomas can be divided into three histogenetic types: (1) invasive melanoma with superficial spreading, (2) nodular melanoma, and (3) invasive melanoma originating from the melanotic freckle of Hutchinson. The depth of invasion can be divided into five stages. Among 48 patients with invasive primary melanoma, there were 30 melanomas with superficial spreading, 12 nodular melanomas, and 6 unclassified types. In 29/33 patients in whom cytological analyses were made, the findings corresponded to the pathohistological ones; in 3 patients, the findings were suspect, and in 1 they were falsely negative. Most (11) patients had polygonal melanocytes; fusiform melanocytes were found in 5 patients, and mixed-type melanocytes in 9. In 4 patients, the cells were polymorphic. (14 refs)

- 79-5881 Familial Hereditary Malignant Melanoma. (Ger) Landthaler, M. (Dermatologische Universitätsklinik,

Frauenlobstrasse 9, D-8000 Munich 2, W. Germany); Braun-Falco, O. *Med Klin* 74(10): 353-357; 1979.

The frequency of familial hereditary malignant melanoma (MM) is estimated to be 1%-7% of all MM's. It occurs by an autosomal-dominant mode of inheritance with reduced penetrance or a polygenetic mode of inheritance. Patients with numerous inherited atypical nevi, the so called BK moles, are reported to have a high incidence of MM. Hereditary MM's begin early in life, are often multiple, and are associated with other malignant tumors in afflicted families. Men are affected as often as women. Five families with hereditary MM are described, and the literature is reviewed. (49 refs)

- 79-5882 Multiple Juvenile Melanoma in a Large Melanotic Birthmark. (Ita) Muscianese, V. (IV Divisione, Sezione Pediatrica, Istituto Dermatologico dell'Immacolata, Rome, Italy); Paradisi, M.; Voglino, A.; Carbone, F. *Chronica Dermatol* 9(6): 643-650; 1978.

A case of multiple juvenile melanoma in a large melanotic birthmark on the right cheek of a 16-mo-old child is reported. A few days after birth, a small pigmented nevus appeared on the cheek. The lesion was initially smooth and reddish grey, but with time it developed into a grey-black, slightly wartlike lesion that covered the entire parotid region. At 11 mo of age, small rose-colored papules appeared in the area; over a 4- to 5-mo period, they reached the size of a lentil. On presentation, the slightly raised lesion had regular margins and about 30 reddish grey papules (2- to 5-mm in diameter) distributed over its surface. All the laboratory tests were negative or within normal limits. Histological examination revealed hyperplasia of the melanocytes. In the dermis, numerous nevus cells were seen, and within the lesion, nodules that contained little or no pigment were observed. A few lymphocytes were seen along the margins of the nodules. The lesion had the characteristics of Spitz nevus. (23 refs)

- 79-5883 Idiopathic Retroperitoneal Fibrosis in Children. (Eng) Chan, S. L. (Urology Clinic, Univ. British Columbia, Vancouver, British Columbia); Johnson, H. W.; McLoughlin, M. G. *J Urol* 122(1): 103-104; 1979.

A case of idiopathic retroperitoneal fibrosis (IRF) in an 11-yr-old boy is presented. A review of seven previous cases in children revealed that there was no characteristic presentation in this disease process and that the diagnosis usually is suspected on an excretory urogram. In adults, IRF has been associated with occult malignancy, which has been implicated as a causative agent in this retroperitoneal process. (10 refs)

- 79-5884 Cutaneous Lupus Erythematosus Associated With Melanoma and BCG Vaccine Therapy. (Eng) Herstoff, J. K. (Div. Dermatology, Dept. Medicine, Roger Williams General Hosp., Providence, RI); Bogaars, H. A. *Arch Dermatol* 115(7): 856-859; 1979.

Two cases of the development of cutaneous lupus erythematosus (LE) after the appearance of a melanoma are reported. A 53-yr-old man was treated with intradermal BCG vaccine and ibuprofen therapy for widespread Stage II metastatic melanoma. LE erupted shortly after the commencement of BCG therapy, but did not sub-

side when the drug therapy was discontinued. In a 67-yr-old man with more localized Stage II melanoma, LE subsided after the melanoma was excised. Neither patient had symptoms of systemic LE and, in general, laboratory data did not suggest visceral disease. However, results of direct immunofluorescence assay demonstrated immunoglobulin deposits and complement in the uninvolved, sun-exposed skin of both patients. Neither patient manifested renal involvement. The first patient had positive serum antinuclear antibody (ANA) results in low titer, and the second did not have ANA in his serum. (14 refs)

- 79-5885 Epitheloid Sarcoma: A Case Report. (Eng) Button, M. (4511 S.E. Hawthorne Blvd., Portland, OR 97215). *J Hand Surgery* 4(4): 368-371; 1979.

A case of epitheloid sarcoma of the pulp of the thumb developed following repeated penetrating injuries. The patient first sustained a penetrating injury to the pulp of the thumb from a clean, broken pipette. The wound healed and became asymptomatic, but a similar injury to the same area occurred 12 yr later and resulted in a slowly enlarging mass; the mass and glass fragments were removed, but recurrence and diagnosis of epitheloid sarcoma upon review of the slides of the initial specimen necessitated amputation of the thumb. (14 refs)

- 79-5886 Ultrastructural Studies on Osteoclastoma. (Eng) Panicker, K. N. (Tata Memorial Centre, Bombay 400 012, India); Potdar, G. G.; Sirsat, S. M. *Indian J Exp Biol* 17(1): 9-14; 1979.

Five biopsy specimens of osteoclastoma of the bone were studied light and electron microscopically. The specimens were comprised of polygonal stromal cells, fibroblasts, lipid-laden foam cells, and multinucleated giant cells. The giant cells showed ultrastructural evidence of phagocytic activity. The other cell types were morphologically more differentiated than the giant cells. Ultrastructural study confirmed the possible origin of this tumor from undifferentiated mesenchymal cells through an intermediate advanced type of cell, the osteoclast. The term "osteoclastoma" is more suitable than "giant cell tumor" and it avoids confusion regarding the origin of this tumor entity. (10 refs)

- 79-5887 Spindle Cell Carcinoma Arising in Chronic Osteomyelitis. A Case Report and Re-assessment of the Literature. (Eng) Hill, J. A. (Dept. Orthopaedic Surgery, Northwestern Univ. Medical Sch., 303 East Chicago Avenue, Chicago, IL 60611); Battifora, H. A.; Milgram, J. W. *Bull Hosp Joint Dis* 39(2): 187-195; 1979.

The occurrence of spindle cell carcinoma is reported in a 65-yr-old woman who had chronic osteomyelitis of the left tibia since the age 12 yr. Biopsy of the sinus tract led to a pathological diagnosis of sarcoma, type unknown, with areas of poorly differentiated epidermoid carcinoma. The patient subsequently underwent left above-knee amputation; the predominant pattern in the surgical specimen was short, criss-crossing fascicles of pleomorphic spindle cells with occasional atypical multinucleated giant cells. Although there were many light microscopic features suggestive of a sarcoma, in particular angiosarcoma, the ultrastructural features were suggestive of epithelial histogenesis. A diagnosis of spindle cell carcinoma was made. The patient did well after surgery with

no evidence of metastases or local recurrence 1 yr later. Electron microscopy may be useful in differentiating true fibrosarcoma from spindle cell carcinoma arising in chronic osteomyelitis. (17 refs)

- 79-5888 Cancer of the Larynx in Women. (Fre) Perrin, C. (Service O.R.L., C.H.U. de Nancy-Brabois, 54500 Vandoeuvre-les-Nancy, France); Long, F. X. *J Fr Otorhinolaryngol* 28(5): 291-294, 297; 1979.

Among a series of 160 patients with cancer of the larynx, eight were women aged 47-84 yr. These women were heavy smokers, at least 20 g/day, and some also used alcohol heavily. Three patients had a family history of ear, nose, and throat cancer. The duration of symptoms (primarily dysphagia) prior to diagnosis ranged from 1 mo (2 patients) to 3 yr (1 patient). Seven women had a differentiated epidermoid carcinoma, and one had an atypical carcinoma. In one patient, the lesion was limited to one ventricular band; however, leukoplakia was observed on the other band. The lesions were extensive in three patients, involving both the hyper- and hypopharynx. In three patients, the cancers involved one side of the larynx and bordered on the adjacent piriform sinus; in one, the cancer involved the entire endolarynx. (no refs)

- 79-5889 Characteristic Features of Laryngeal Carcinoma in Women. (Rus) Iudov, N. N. (Dept. Otorhinolaryngology, Medical Inst. Altai Krai, Altai Krai, USSR); Zavarzin, A. A.; Simonova, I. A. *Vestn Otorinolaringol* (4): 53-55; 1979.

Clinical findings in a group of 100 female laryngeal cancer patients (aged 23 to 86 yr; median age group 50-59 yr) and 300 male patients were compared. It was found that 62% of the women smoked and 39% consumed alcohol, compared with 92% and 80%, respectively, of the men; precancerous lesions of the larynx were diagnosed in 17% of the women and 18% of the men. Regional lymph node metastases were detected in 10% of the women and 18.7% of the men. The women had a better 5-yr survival rate. (11 refs)

- 79-5890 Study of Amylase-producing Lung Cancer. (Jpn) Fukuda, H. (Dept. Thoracic Surgery, Chest Disease Res. Inst., Kyoto Univ., Kyoto, Japan); Ito, M. *Bull Chest Dis Res Inst Kyoto Univ* 12(1/2): 36-45; 1979.

Amylase activity in the resected tumor tissue of lung cancer patients was investigated biochemically, microscopically, histologically, and immunohistochemically. The subjects included 8 patients with adenocarcinoma, 7 with squamous cell carcinoma, 3 with undifferentiated carcinoma, and 1 with cylindroma. Controls were patients who underwent lung, bronchial, liver, or pancreatic resection. Compared with controls, only 2/8 adenocarcinoma specimens showed high amylase activity. Electron microscopic examination revealed small zymogen granulelike vacuoles and free ribosomes in the amylase-producing tumor cells. These cells showed a specific fluorescence for amylase with an alcian blue stain. The serous cells of the bronchial gland of control adults and fetuses also showed a specific fluorescence for amylase, as did certain peripheral cells of fetal lung tissue. The origin of the amylase-producing cells in patients with adenocarcinoma of the

lung may be the serous cells of the bronchial gland and certain peripheral lung cells. (20 refs)

- 79-5891 Histologic and Ultrastructural Features of the Clara Cell Adenoma of the Mouse Lung. (Eng) Kauffman, S. L. (Dept. Pathology, State Univ. New York, Brooklyn, NY); Alexander, L.; Sass, L. *Lab Invest* 40(6): 708-716; 1979.

Lung adenomas were induced by the transplacental exposure of Swiss Bagg-Webster mice to ethylnitrosourea (0.75 mM/kg ip) on the 16th day of gestation. The lungs of postnatal animals 1-3 mo of age were examined grossly, and step sections were made of the right lower lobe for light microscopy. Additional tumors were fixed in Palade's solution and prepared for light and electron microscopy. Tumors were classified on the basis of their predominant histologic pattern as alveolar or bronchiolar, and the tumor cell type was identified by electron microscopy. Of the 149 adenomas found in the right lower lobes, 86 were bronchiolar and 61 were alveolar. The bronchiolar papillary tumors consisted of Clara cells, the nonciliated epithelial cell of the terminal bronchioles, whereas the alveolar tumors consisted of type II alveolar cells. The Clara cell has not previously been recognized as a progenitor cell of murine lung adenomas; however, these cells form tumors that are clearly distinguishable from type II alveolar cell adenomas. Because the Clara cell tumor may have a malignant potential not shared by the type II cell adenoma, it is important to classify mouse lung adenomas according to their cell of origin, particularly when evaluating the progression of chemically induced tumors. (59 refs)

- 79-5892 Pulmonary Siderosis and Bronchopulmonary Cancer. A Case Report. (Fre) Caillard, J. F. (Institut de médecine du travail, C.H.U. de Caen, Caen, France); Lemenager, J.; Wyplotz, J.; Mandard, J. C.; Chasles, J.; Benard, Y.; Le Bouffant, L. *Arch Mal Prof* 40(1/2): 52-53; 1979.

An aggregated form of pulmonary siderosis and a 5- to 6-cm adenocarcinoma of the right upper lobe were diagnosed in a 51-yr-old metal polisher who had been exposed to iron and iron oxide dust for >15 yr. An inflammatory pseudotumor was found in the lingula of the left upper lobe. (no refs)

- 79-5893 Pleomorphic Pulmonary Hamartoma. An Apparently Unique Variant of Pulmonary Hamartoma. (Eng) Gisser, S. D. (Dept. Pathology, Cooper Medical Center, Camden, NJ); Young, I. *Hum Pathol* 10(4): 393-403; 1979.

A well-circumscribed, nonencapsulated, noninvasive tumor discovered accidentally in the lung of a 41-yr-old black man is described. The patient had been a moderate smoker for 20 yr. The tumor was associated with anomalous lung segmentation and the bronchial and blood supply to the lung. The tumor appeared to be undifferentiated, and light microscopy alone led to various erroneous diagnoses, including neurilemoma, leiomyoma, ganglioneuroblastoma, and teratoma. Electron microscopy showed a highly complex but incompletely organized array of cellular elements similar to those seen in mature and developing pulmonary tissue. These elements included well-differentiated epithelial elements, some ciliated and some mucin-producing, as well as undifferentiated mesenchyme. The mass represented a unique, probably hamartomatous, tumor. (15 refs)

- 79-5894 Scleroderma with Carcinoma of the Esophagus. Case Report. (Eng) Whitaker, J. A. (Dept. Gastroenterology, Wesley Medical Center, 550 N. Hillside, Wichita, KS 67214); Bishop, R. *Am J Gastroenterol* 71(5): 496-500; 1979.

An esophageal carcinoma developed in a 48-yr-old man with scleroderma. An antiesophageal regimen was instituted. The patient was readmitted 23 mo later with dysphagia, wt loss, and substernal chest pains. A barium swallow revealed a fungating lesion that nearly obstructed the esophagus. Biopsy of a nodular mass proved to be a moderately differentiated squamous cell carcinoma. Despite the fact that the esophagus of scleroderma patients is chronically irritated because of acid reflux, the development of esophageal carcinoma in these patients probably is a rare event. (26 refs)

- 79-5895 Zenker's Diverticulum. Carcinoma of the Esophagus? (Eng) Rojas, F. A. (Dept. Otolaryngology, Henry Ford Hosp., 2799 W. Grand Boulevard, Detroit, MI 48202); Szymanowski, R.; Fujita, S. *J Otolaryngol* 8(3): 266-270; 1979.

The case of a 67-yr-old man who developed a squamous cell carcinoma in a Zenker's diverticulum is reported. The patient presented with dysphagia of several mo duration. There was an associated regurgitation of food that had become more severe the month before admission. An esophagram revealed a Zenker's diverticulum, but no tumor or mucosal abnormality was detected by hypopharyngoscopy and esophagoscopy prior to surgery. The diverticulum was excised and found to be infiltrated by squamous cell carcinoma. Radiotherapy consisting of 6,000 R over a 6 wk period was administered. Five months after the first admission, the patient was again suffering from progressive dysphagia. Laryngoscopy and esophagoscopy showed a friable mass (6 x 5 cm) in the hypopharynx and upper esophagus, and histological examination revealed well-differentiated epidermoid carcinoma. A laryngopharyngectomy with partial esophagectomy was performed. (13 refs)

- 79-5896 Gastric Polyps. (Ita) Ciciliot, V. (Ente Ospedaliero San Paolo, Ospedale Generale Provinciale, Savona, Italy); Roggero, F.; Grandis, C.; Oliveri, M. *Minerva Dietol Gastroenterol* 25(2): 209-222; 1979.

The occurrence, description, and classification of gastric polyps and tumors are reviewed, with particular reference to 24 cases encountered during 2,450 instances of gastric surgery. Most (60%-70%) gastric polyps are of epithelial origin. They are of four types: submucosal masses (benign), types I and III sessile polyps (each, benign and malignant), and pedunculated polyps (benign and malignant). Leiomyomas are the most frequent nonepithelial gastric tumors; however, their incidence is quite variable in different literature reports. Leiomyoblastomas are usually benign gastric tumors of muscular origin, and they show microfibrils microscopically. Lipomas represent 0.06%-7.2% of all benign gastric tumors; they are usually localized in the antrum, where they arise from connective tissue. Three types of nervous system tumors occur in the stomach. Neurilemmomas, which represent about 70% of these tumors, occur most frequently in the distal portion of the stomach, arising from myelinated fibers. Neurofibromas represent about 25% of nervous system gastric tumors, and they arise generally throughout the stomach. The remaining 5% of nervous system gastric tumors are neuroblastomas and paragangliomas,

which arise in the sympathetic nervous system. Gastric tumors containing pancreatic elements, gastric vascular tumors, and gastric fibromas also occur. The 24 patients (14 women and 10 men aged 45-88 yr) had histologic diagnoses of adenomatous polyps (12 cases), polyps with malignant change (5), leiomyomas (2), a pancreatic-type tumor, a fibromyoma, a leiomyoblastoma, a lipoma, and a granuloma. Clinical data for these patients are tabulated. (58 refs)

- 79-5897 Peptic Esophagitis and Carcinoma of the Lower Third of the Esophagus: Report of 7 Cases. (Fre) Hureau, J. (Clinique Therapeutique Chirurgicale, Hopital de Vaugirard, 389, rue de Vaugirard, 75-Paris, France); Bourdais, J. P.; Delavierre, P.; Vayre, P. *J Chir (Paris)* 116(3): 167-174; 1979.

Carcinoma of the lower third of the esophagus was diagnosed in 7 patients (4 men and 3 women, aged 41-82 yr) with chronic peptic esophagitis. The tumor was identified as adenocarcinoma in 5 cases, as epidermoid carcinoma in 1, and as epidermoid carcinoma in situ in another. The duration of the esophagitis before the diagnosis of the carcinoma could be established in 5 cases, ranging from 6 to 32 yr in 4, and probably 3-5 mo in 1. The findings indicate that peptic esophagitis of the lower third of the esophagus can be precancerous and that chronic cases require regular follow-up. (35 refs)

- 79-5898 Esophagogastroplasty in Upper Esophageal Lesions: 4 Cases. (Ita) Olivero, S. (Istituto di Chirurgia d'Urgenza, Università degli Studi di Torino, Turin, Italy); Ibba, F.; Viglione, G. C.; Sanfelici, G.; Foco, A.; Garbarini, A.; Bertoldo, U.; Serenitha, U.; Bronsino, E.; Buniato, E.; Vottero, G. *Minerva Chir* 34(7): 511-524; 1979.

An esophagogastroplasty was performed in four patients, three with a neoplastic lesion of the upper esophagus and one with mediastinal compression due to sclerosing mediastinitis. The technique is described in detail, and indications for the surgery are given. (15 refs)

- 79-5899 Identical Malignant Tumors in Siblings and Twins. (Hun) Cserhati, G. (Sebeszeti Osztaly, Varosi Korhaz, Mosonmagyaróvár, Hungary); Szilagyi, J. *Orv Hetil* 120(20): 1195-1196; 1979.

Rectal adenocarcinomas were diagnosed in 69-yr-old twin brothers within 22 days. Both patients had blood type AB and were Rh-positive. Inoperable malignant gastric tumors of the same localization were found in two brothers aged 60 and 63 yr, respectively. Both had blood type A and were Rh-positive. The tumors were not classified histologically. The findings suggest that these tumors had a genetic origin. (4 refs)

- 79-5900 Successful Surgery for Malignant Neurinoma Originating in the Stomach. (Hun) Zolnay, B. (Sebeszeti Osztaly, Semmelweis Korhaz, Miskolc, Hungary); Radvanyi, G.; Kostyal, A. *Orv Hetil* 120(24): 1449-1451; 1979.

A malignant neurinoma originating in the muscular layer of the gastric mucosa was diagnosed in a 66-yr-old man 12 yr after

Billroth II resection for duodenal ulcer and pyloric stenosis. The subserous tumor contained necrotic Schwann's cells. (20 refs)

- 79-5901 Leiomyosarcoma of the Duodenum. Case Report and Literature Review. (Spa) Costa Baptista, J. C. (Dept. de Cir., Fac. de Med., Hosp. de Clin., Marilia, Spain); Gerlach, S. M.; Gomes de Oliveira, G.; Tsuji, H.; Ribeiro de Melo, N.; Nakadaira, A. *AMB* 25(1): 28-30; 1979.

A rare case of leiomyosarcoma of the duodenum in a 59-yr-old man is presented. The patient was admitted with intense pain in the right iliac fossa and a 6 mo history of wt loss. He had undergone gastrectomy for duodenal ulcer 16 yr previously. Ten years previously, he had been hospitalized for interorrhagia, and a tumor 5 cm in diameter was observed in the right abdomen. Two years before diagnosis of the leiomyosarcoma, the tumor had increased to 10 cm in diameter and it was tender. The etiology, incidence, pathology, and diagnosis of duodenal leiomyosarcomas are discussed. (27 refs)

- 79-5902 In-Vitro Evidence for Adenoma-Carcinoma Sequence in Large Bowel (Letter to Editor). (Eng) Danes, B. S. (Lab. Cell Biology, Dept. Medicine, Cornell Univ. Medical Coll., New York, NY 10021). *Lancet* 2(8132): 44-45; 1979.

In vitro evidence for a progression from normal tissue to adenoma to carcinoma in the large bowel was obtained using cell lines established from the skin of 112 patients with adenomatosis of the colon and rectum (ACR) and 74 age- and sex-matched controls. Transformed cell populations growing in suspension arose in single monolayer sublines derived from five biopsies from four ACR patients. The changes indicative of transformation included altered morphology, ability to grow as single cells or clusters in suspension and on a surface, and a seemingly unlimited life-span in culture. The occurrence of transformed cell populations in some ACR sublines and not in those from controls supports the hypothesis that cells with genomes having certain mutations, such as the polyposis gene, are more susceptible than those without such mutations to changes in biological properties in vitro. The cellular changes noted in this study could be considered as just one in a series of changes that precede cancer. (3 refs)

- 79-5903 Anatomic, Pathologic, and Clinical Aspects of a Case of Carcinoid of the Ileum. (Ita) Sgro, M. (Divisione di Chirurgia Generale, Ospedale di Circolo, Busto Arsizio, Italy). *Minerva Chir* 34(7): 543-548; 1979.

The anatomopathological and clinical aspects of a case of carcinoid of the ileum that occurred in a 65-yr-old patient are presented. Attention is called to new histogenetic theories and classification criteria in the light of recent immunohistochemical, ultrastructural, and biochemical research. (27 refs)

- 79-5904 Leiomyosarcoma of the Jejunum with Lymphatic Dissemination. Report of a Case. (Por) Oliveira Almeida, H. (Dep. de Patol, Fac. de Med. do Triangulo Mineiro, Uberaba, Brazil); de Andrade, J. I.; Maluf, W.; Naves Junqueira, J. F. *AMB* 25(1): 18-20; 1979.

A rare case of well-differentiated leiomyosarcoma of the jejunum with lymph node metastases occurred in a 51-yr-old man. The differential diagnosis of this tumor from a benign leiomyosarcoma is very difficult. The histological data suggestive of malignancy in this case were moderate hypercellularity and irregular distribution of mitoses. (20 refs)

- 79-5905 Multiple Carcinoids of the Small Intestine. (Ger) Ernst, P. (Chirurgische Klinik, Städtisches Krankenhaus Berlin-Pankow, Galenus-strasse 60, 110 Berlin, W. Germany); Koch, P.; Bailleu, E. *Z Aerztl Fortbild (Jena)* 73(9): 448-450; 1979.

The difficulty of preoperative diagnosis of a carcinoid in the small intestine is illustrated by a case report of multiple carcinoids in a 75-yr-old woman who presented with diffuse peritonitis. This patient had suffered from spastic diarrhea and occasional constipation for several years, and she had recently undergone surgery for subileus. (16 refs)

- 79-5906 Malignant Transformation of Adenoma of Large Intestine. (Jpn) Yamagiwa, H. (Dept. Clinical Pathology, Mie Univ. Sch. Medicine, Tsu, Japan); Ishihara, A. *Jpn J Cancer Clin* 25(7): 664-668; 1979.

A histological examination was made of 623 resected tumors from 600 patients with carcinoma of the large intestine (LIC: 54 early stage) and of 635 adenomas that were surgical, endoscopic, or autopsy specimens to determine the relationship between the adenomas found in large bowel polyps and LIC. Adenomas were found in 62/623 LIC's, and malignant transformation was seen in 62/697 adenomas found in areas of the malignant tumors. Adenomas >1 cm diameter, found most often in the rectum and sigmoid flexure, had a greater degree of atypia than those with a diameter of <1 cm. Malignant transformation was seen in 5.2% of the tubular adenomas, 78.9% of the tubulovillous adenomas, and 65% of the villous adenomas. Adenomas up to 1 cm in diameter showed very few malignant cells (approx 1%), and adenomas >1 cm showed increasing numbers of malignant cells. In contrast, villous adenomas, which occurred frequently in the rectum and sigmoid flexure, showed no signs of transformation up to a diameter of 4 cm. The incidence of remnants of adenomas was related to the depth of tumor infiltration; it was 93.1%, 64%, 15.3%, and 1.7% with mucosal, submucosal, muscular, and serosal invasion, respectively. (17 refs)

- 79-5907 Malignant Lymphoma in Chronic Ulcerative Colitis. (Yug) Branica, H. (Odjel za patologiju i citologiju, Opca bolnica, Split, Yugoslavia); Bakotin, J.; Rubic, I. *Lijec Vjesn* 101(2): 88-90; 1979.

The case report of a 36-yr-old man who had chronic ulcerative colitis for 6 yr is given. Total proctocolectomy was performed because of repeated attacks of abdominal pain and diarrhea. The histopathologic report was chronic ulcerative colitis and non-Hodgkin's-type malignant lymphoma. The clinicopathologic aspects of this complication of ulcerative colitis are discussed, with special emphasis on the problem of correct diagnosis. (15 refs)

- 79-5908 Extramedullary Plasmacytoma of the Gastrointestinal Tract in a Renal Transplant Recipient. (Eng) Hara, H.

(Dept. Pathology, Kochi Medical Sch., Nankoku City, Kochi Prefecture 781-51, Japan); Yamane, T.; Yamashita, K. *Acta Pathol Jpn* 29(4): 661-668; 1979.

An extramedullary plasmacytoma (PC) of the gastrointestinal tract that developed in a 23-yr-old male renal transplant recipient was examined by an immunoglobulin (Ig)-enzyme bridge technique. Formalin-fixed, paraffin-embedded tissue sections were stained successively with specific rabbit anti-human IgG, IgA, and IgM and κ light chain antisera, goat anti-rabbit IgG antisera, and rabbit anti-horseradish peroxidase antisera. Most of the plasma cells in the gastric mucosa contained a single type of heavy-chain IgA and κ -type light chain, whereas plasma cells in the kidneys and liver were well-stained with various types of Ig. Pathological investigations revealed multiple similar tumors in the ileum, cecum, and ascending colon, suggestive of a multicentric origin. The patient had been treated with immunosuppressive agents after the renal transplant, and he appeared to be in an immune-deficient state. The development of the plasma PC might be an indirect complication of the renal transplantation or it might be related to the immune-deficient state. (16 refs)

79-5909 Rectal Polyp: A Preliminary Stage of Rectal Carcinoma? (Ger) Wayand, W. (I. Chirurgische Universitätsklinik, Alser Strasse 4, A-1097 Vienna, Austria); Roka, R. *Acta Chir Austriaca* 10(5): 113-115; 1979.

Seventy-three rectal polyps from 67 patients with solitary polyps of the rectum (Group 1) and 93 rectal polyps from 74 patients with rectal carcinoma (Group 2) were investigated for signs of malignant transformation. The incidence of atypia, increased number of mitoses, and so-called carcinoma in situ was 5/73 in Group 1 and 14/97 in Group 2. Invasion was seen in Group 1 (3/73 polyps) and in Group 2 (6/97 polyps). Most Group 1 patients were 55-64 yr old, and most Group 2 patients were 65-74 yr old. Eight polyps from Group 1 and 20 from Group 2 were investigated for type of dedifferentiation. In Group 1, 2 tubulovillous, 4 villous, and 2 tubulovillous polyps were found. In Group 2, 6 tubulovillous, 7 villous, and 7 tubulovillous polyps were found. The difference in the age distribution between the two groups suggests that rectal polyps evolve into carcinoma. (10 refs)

79-5910 Familial Urinary Bladder Cancer. (Eng) Purtilo, D. T. (Dept. Pathology, 55 Lake Avenue North, Univ. Massachusetts Medical Sch., Worcester, MA 01605); McCarthy, B.; Yang, J. P.; Friedell, G. H. *Semin Oncol* 6(2): 254-256; 1979.

The clinical and pathological features of 13 cases of bladder transitional cell carcinoma (TCC) in 6 unrelated families in the Worcester, Massachusetts, area illustrate the contention that genetic factors may play an important role in the etiology of bladder TCC. The affected individuals were two male siblings (aged 62 and 55 yr respectively at time of onset) in family 1, two male siblings (aged 59 and 56 yr) in family 2, brother and sister (aged 91 and 89 yr) in family 3, two male siblings (aged 39 and 52 yr) and family 4, two brothers and a daughter of the first brother (aged 33, 28, and 19 yr) in family 5, and a father and son (aged 73 and 62) in family 6. Occupational and smoking habit risks were prevalent in all these patients except those in family 3, the 52-yr-old patient in family 4, and the 19-yr-old patient in family 5. These cases of TCC displayed the major features of familial cancer: 1) affected individuals were younger than the usual non-familial cases; 2) multiple TCC with frequent recurrences and multiple genitourinary car-

cinomas occurred in families 3 and 4; 3) there was general concordance in types of cancer; and 4) there was concordance of age at time of appearance of TCC in siblings. The pattern of inheritance in families 5 and 6 suggests a Mendelian autosomal dominant trait. The possibility that an inherited predisposition to bladder TCC or a heightened susceptibility to environmental carcinogens operates in familial cases of bladder TCC is discussed. (18 refs)

79-5911 Nonpapillary Carcinoma In Situ of the Urinary Bladder. A Histopathologic Study and Mapping of the Urothelial Lesions. (Eng) Iwasaki, H. (Dept. Pathology, Fukuoka Univ. Sch. Medicine, 34 Nanakuma, Nishi-ku, Fukuoka 814, Japan); Enjoji, M.; Kano, M. *Acta Pathol Jpn* 29(4): 623-633; 1979.

Three cases of primary carcinoma in situ (CIS) of the bladder diagnosed by urinary cytology and multiple biopsies were studied in detail. In two cases, epithelial lesions were mapped completely to study the distribution of abnormal epithelium and to demonstrate the presence or absence of microscopic invasion. The patients, all men aged 53-66, had no histories of exposure to carcinogens; however, all three were smokers. Atypical hyperplasia and CIS with foci of microscopic invasion affected the bladder mucosa and extended continuously to the distal ureters and the prostatic urethra. A multicentric distribution of abnormal epithelium was definite in one patient, and the bladder mucosa was denuded extensively in another. Metastasis to one of the regional lymph nodes was noted in the third patient. Pagetoid cells that possessed abundant clear cytoplasm were found in two of the patients. They were found most frequently in the Brunn's nests and in the developing margin of the CIS. Their origin is obscure. They may represent transformed tumor cells showing differentiation toward the surface umbrella cells or they may be derived from Brunn's nests, where the cells may gain potential to differentiate to glandular epithelium. The finding in one patient of CIS in small isolated foci and in a single large area separated by nonneoplastic mucosa and often intermingled with atypical epithelium supports the multicentric origin of CIS and indicates its intimate relationship to atypical epithelium. (18 refs)

79-5912 The Spectrum of Hepatic Dysfunction in Inflammatory Bowel Disease. (Eng) Dew, M. J. (Nutritional and Intestinal Unit, General Hosp., Steelhouse Lane, Birmingham B4 6NH, England); Thompson, H.; Allan, R. N. *Q J Med* 48(189): 113-135; 1979.

A study of the incidence and nature of hepatic dysfunction among 1,237 patients with inflammatory bowel diseases revealed the development of biliary tree carcinoma in eight patients with longstanding total colitis. Two had been treated with panproctocolectomy many years before the onset of biliary tree obstruction. Three patients had established liver disease complicated by biliary tract carcinoma. (61 refs)

79-5913 Bilateral Wilms's Tumour in Klippel-Trenaunay Syndrome (Letter to Editor). (Eng) Ehrich, J. H. (Kinderklinik, Institut fuer Pathologie, Medizinische Hochschule Hannover, Karl Wiechert Allee 9, 3000 Hannover 61, W. Germany); Ostertag, H.; Flatz, S.; Kamran, D. *Arch Dis Child* 54(5): 405; 1979.

Bilateral Wilms' tumor in a 1-yr-old girl with the Klippel-Trenaunay syndrome is reported. At laparotomy, a nodular tumor originating from the left kidney was found, and the kidney was removed. This kidney, plus biopsy specimens taken from nodules on the right kidney, showed glomerular and tubular differentiation and solid blastomatous structures consistent with Wilms' tumor. (1 ref)

79-5914 Erythropoietin Levels in the Course of a Patient with Erythropoietin-producing Renal Cell Carcinoma and Transplantation of This Tumor in Nude Mice. (Eng) Toyama, K. (Dept. Internal Medicine, Sch. Medicine, Keio Univ., 35 Shinanomachi, Shinjuku-ku, Tokyo, Japan); Fujiyama, N.; Suzuki, H.; Chen, T. P.; Tamaoki, N.; Ueyama, Y. *Blood* 54(1): 245-253; 1979.

Erythropoietin (EP) was measured by the exhypoxic polycythemic mouse method during the course of renal cell carcinoma associated with erythrocytosis in a 64-yr-old man. The serum EP level fluctuated with progression of the disease. The originally high level [0.11 units (U)/ml] decreased after nephrectomy and then increased again with the development of a lung metastasis (0.1 U/ml). EP was markedly increased in extracts from primary renal cell carcinoma (0.2 U/g) and lung metastasis (0.8 U/g). Cells from the lung metastasis were transplanted into nude mice, resulting in erythrocytosis in some animals. In the erythrocytotic mice, EP was elevated to levels of 0.25-0.9 U/g in the tumor tissues and 0.67 U/ml in the serum. The results indicate that the renal cell carcinoma of this patient was an EP-producing tumor. (15 refs)

79-5915 Grafts of Ehrlich's Adenocarcinoma in Normal and Hypertrophic Mouse Kidneys. (Ita) Michelazzi, A. (Istituto di patologia generale, Università di Genova, Genoa, Italy); Burlando, F. *Pathologica* 71(1012): 195-199; 1979.

Success in grafting Ehrlich's adenocarcinoma in normal and hypertrophic kidneys of Swiss mice was investigated. The results were different during the different stages of hypertrophy: positive takes were few and limited to a narrow area of the parenchyma on days 10-12 during the development of hypertrophy, but when hypertrophy had been achieved, the take rate was similar to that in normal kidneys. Tumor cells and cells that are becoming hypertrophic may compete for metabolic substrates. (1 ref)

79-5916 Hepatoblastoma with Adenomatoid Renal Epithelium. (Eng) Knowlson, G. T. (Dept. Pathology, Birmingham Children's Hosp., Ladywood Middleway, Ladywood, Birmingham B16 8ET, England); Cameron, A. H. *Histopathology* 3(3): 201-208; 1979.

A hepatoblastoma (HB) occurred in a male infant with a renal malformation involving adenomatoid epithelium lining the Bowman's capsule and the adjacent part of the proximal tubule. The infant, born after a normal full-term pregnancy without drug therapy, was mildly jaundiced at 20 hr of age; his abdomen was distended and there was hepatomegaly. The blood level of α -fetoprotein was markedly elevated at 1,280 mg/liter. The tentative diagnosis of HB was confirmed by a liver scan that showed a posterior filling defect in the right lobe. During a right lobectomy at age 5 wk, the child's blood pressure fell suddenly, he sustained cardiac arrest, and he could not be revived. The 7-cm tumor was round, well-defined, unencapsulated, and reddish in color, and it consisted histologically of rather well-differentiated liver cells.

Postmortem examination showed kidneys of normal size, but their combined wt was 45 g (normal, 34 g). Histologically, in about 50% of the glomeruli throughout the cortex, Bowman's capsule was dilated and the parietal epithelium was formed by a primitive epithelium composed mainly of columnar but, in some places, of spindle-shaped cells. This abnormal parietal epithelium extended into the adjoining part of the proximal tubules, some of which apparently had double entrances. It is concluded that HB is a malignant tumor related to developmental abnormalities. Adenomatoid transformation of the parietal glomerular epithelium may be a manifestation of aberrant development and may predispose to HB and, perhaps, other tumors. (19 refs)

79-5917 Multiple Primary Tumors in Patients with Genital Cancer. (Fre) Quereux, C. (Service de Gynécologie-Obstétrique, C.H.U., 45 rue Cognacq-Jay, 51090 Reims cedex, France); Dorangeon, P.; Wahl, P. *Gynecologie* 30(1): 74-82; 1979.

In a series of 379 patients with genital cancers, 14 had multiple cancers fulfilling the following criteria: different histology for each tumor, different organs involved, metastases appropriate to each tumor. The patients ranged in age from 49 to 67 yr. Two of the patients had tumors confined to the genital region, and six had genital cancers associated with cancers of other organs, including the breast, colon, and anus. An additional five patients had multifocal cancers of the upper genital tract, and one had multiple cancers of the lower genital tract. The cancers were diagnosed simultaneously in all but three patients, in whom the interval between the first and second cancers was 10 mo for two and 15 yr for the third. Only 6/14 patients survived for a significant period of time (4 mo to 13 yr) after diagnosis. (21 refs)

79-5918 Morphogenesis of Ovarian Cystomas. (Rus) Serov, S. F. (Lab. Pathomorphology, N. N. Petrov Res. Inst. Oncology, Leningrad, USSR); Irzhanov, S. I.; Bychkov, V. M.; Zagol'skaia, V. N. *Vopr Onkol* 25(6): 29-36; 1979.

The results of a morphological examination of 1,385 serous ovarian cystoma specimens are presented. There were 467 benign, 125 intermediate, and 793 malignant cystomas; the age of the patients ranged from 18 to 82 yr. Cytophotometric analysis showed a progressive increase in ploidy from 3n in the benign tumors to 4n-7n in the intermediate tumors and 6n-10n in the malignant tumors. Electron microscope analysis revealed that the benign cystomas consisted predominantly of monomorphic cuboid cells (71%) and villous cells (18%). Malignant transformation was associated with a progressive decrease in the incidence of villous cells (to 3%-4% in intermediate cystomas) and marked cellular polymorphism. (23 refs)

79-5919 Case Report: Ultrastructure of Mature Neurogenic Implants from Ovarian Immature Teratoma. (Eng) Gonzalez-Campora, R. (Dept. Pathology, Univ. Seville Medical Sch., Seville, Spain); Nogales, F. F.; Davidson, H. G.; Mendez, J. A. *Histopathology* 3(3): 233-240; 1979.

An ultrastructural study was made of mature (Grade 0) neurogenic peritoneal implants from a Grade 1 ovarian immature teratoma. The presence of different types of neuroectodermal cells challenges the current terminology of this lesion ("gliomatosis peritonei", or peritoneal glial implants), which implies that it contains a single proliferating cell type. Light and electron microscopy demonstrated the presence of ependymal glia, central neurons, and

oligodendroglia. The ultrastructural features were indicative of maturity in all cell lines, and even the neurons exhibited well-formed synapses. Marked cytoplasmic fibrillary change, similar to that found in CNS gliosis, was observed in the astrocytes. The ependymal cells had abnormal cilia with an altered configuration and number of microtubules. (13 refs)

- 79-5920 Anterior Segment Metastases from an Ovarian Choriocarcinoma. (Eng) Frank, K. W. (Ophthalmic Pathology Lab., Kresge Eye Inst., 3994 John R St., Detroit, MI 48201); Sugar, H. S.; Sherman, A. I.; Beckman, H.; Thoms, S. *Am J Ophthalmol* 87(6): 778-782; 1979.

The case report of a 28-yr-old woman with ovarian choriocarcinoma metastatic to the anterior segment of the eye is presented. The patient developed a uveitis in the left eye; subsequently, a mass was observed in the anterior segment of that eye together with a subconjunctival mass that appeared to extend from it. Biopsy showed two different cell types consistent with the cytotrophoblastic and syncytiotrophoblastic elements typical of choriocarcinoma. (28 refs)

- 79-5921 Colpocytohistological Aspects of Uterine Condyloma. (Fre) Saurel, J. (Institut d'Histo-Cyto-Pathologie, 15 cours Georges Clemenceau, 33000 Bordeaux, France); Marc, J.; Morard, J. L.; Audebert, A. *Gynecologie* 30(2): 159-166; 1979.

The association of condyloma acuminatum of the cervix, which is due to a papilloma virus, and precancerous conditions is reviewed. From December 1977 to June 1978, 60 cases of cervical condyloma were diagnosed, usually by Papanicolaou smears. The average age of the patients was 33 yr. The condyloma cells were also found in the vagina in 4 patients, in the vulva in 1 patient, and in the endocervix in 7 patients. Cytological surveillance revealed a patient with severe dysplasia of the cervix 3 mo after the initial smear and one with carcinoma in situ at 6 mo. The histological aspects of cells in transition from the hyperkeratotic cells on the surface of the condyloma to carcinoma in situ cells are described. The "halo cell," which has a clear perinuclear halo, is characteristic of the virus-infected cells. The nuclei of these cells are sometimes enlarged, but in general they are small, prepyknotic or pyknotic, with dense, highly colored chromatin. The cytoplasm, which is lightly basophilic or eosinophilic and stains positively with orange dyes, is compressed on the periphery of the cell. According to some authors, the alteration of the halo from a perinuclear to paranuclear conformation indicates the involution of cells with malignant potential. The halo cells were found in all smears in variable numbers. (38 refs)

- 79-5922 Cervical Dysplasias. Analysis of Late Results. (Fre) Gavel, M. (Angoulême, France). *Gynecologie* 30(1): 82-84; 1979.

The occurrence of cancer in 1,915 patients treated for presumably benign lesions of the cervix is reported. The cases were gathered over a 20-yr-period (1953 to 1973). Only patients with dysplasias of the squamous or glandular epithelium or with polyps were included. Four patients developed cancer 7-13 yr after treatment for dysplasias. (no refs)

- 79-5923 Rare Lesions of the Cervix. (Fre) Minh, H. N. (Amiens, France); Smadja, A.; Coupez, F.; Lecomte, P. *Gynecologie* 30(1): 69-72; 1979.

Two patients, both age 23, with papillomas of the cervix and two patients, ages 43 and 62 with Bowen's disease of the cervix are reported. The lesions arose from the cervical malpighian epithelium. Both types of lesions are more likely to be found in the vulva or the vagina, and they have a variable potential for malignancy. (6 refs)

- 79-5924 A Case of Two Different Testicular Tumors. (Pol) Krzakowski, M. (Kliniczny Oddział Radioterapii, Centrum Kształcenia Podyplomowego WAM, ul. Szaserów 128, 00-909 Warsaw, Poland); Alexandrowicz, A.; Majkowski, J.; Nowakowski, W. *Pol Tyg Lek* 34(23): 921-922; 1979.

A malignant teratoma of the testicle was diagnosed in a 21-yr-old man. After orchiectomy, he underwent radiotherapy (total skin dose 4,500 R in 38 days). Another tumor was diagnosed in the remaining testicle 5 yr later: it was a mixed tumor composed of elements of seminoma and mature teratoma. No metastases were seen. (15 refs)

- 79-5925 Scanning Electron Microscopy of In Vitro Grown Cells from Experimentally Induced Neurogenic Tumors. (Eng) Lalitha, V. S. (17 Neelakantamehta St., T. Nagar, Madras-17, India 600017); Mennel, H. D. *Acta Neuropathol (Berl)* 47(1): 61-66; 1979.

Serially transplanted experimental neurogenic tumors were explanted in vitro and analyzed by scanning electron microscopy. The seven tumors used were induced in the offspring of pregnant BD-IX rats treated with ethylnitrosourea (single iv dose on gestation day 15) or with repeated ip doses of methylnitrosourea and estrogen. In explants of intracerebrally transplanted gliomas, small stellate cells with branching processes were observed. In transplanted tumors of the peripheral nervous system, slender bipolar cells as well as fibroblasts emerged. The stereoscopic features were compared with the features revealed by conventional light microscopy. The findings were consistent with the assumption of a glial derivation of CNS tumors induced by neurotropic alkylating carcinogens. The peripheral tumors were composed of Schwann cell-like elements and fibroblasts. (17 refs)

EPIDEMIOLOGY AND BIOMETRY

- 79-5926 Results of a Two-Year Determination of Nitrates in Selected Agricultural Products of Vegetable Origin. (Slo) Kirchhoffova, A. (Okresna hygienicka stanica, Leninova trieda 78, 949 01 Nitra, Czechoslovakia). *Cesk Hyg* 24(5): 251-255; 1979.

Because the high nitrate concentrations that have recently been found in vegetables may be the cause of alimentary methemoglobinemia, particularly in infants, nitrate concentrations were determined in fruits and vegetables. The nitrate concentration ranged between 5.6 and 71.2 mg/100 g, and it was higher in vegetables than in fruits. Nitrate concentrations may be influenced by the presence of nitrogen fertilizer, humidity, rainfall, and light intensity. (7 refs)

- 79-5927 Environmental Radioactivity in Greenland in 1977. (Eng) Aarkrog, A. (Riso Natl. Lab., DK 4000 Roskilde, Denmark); Lippert, J. *Riso* (388): 1-20; 1978.

Fallout radioactivity in Greenland during 1977 was measured. Strontium-90 and, in most cases, cesium-137 were determined in samples of precipitation, sea water, vegetation, animals, and drinking water. The 1977 mean levels of ^{90}Sr and ^{137}Cs in the human diet in Greenland were estimated. The ^{90}Sr level in the diet was 87% of the estimated Danish mean level, and 52% of the Faroese level. The ^{137}Cs level was 4.8 times that in the Danish diet and half that in the Faroese diet. (4 refs)

- 79-5928 Retinoblastoma in Sweden 1958-1971. A Clinical and Histopathological Study. (Eng) Kock, E. (Dept. Ophthalmology, Karolinska Hosp., Stockholm, Sweden); Naeser, P. *Acta Ophthalmol (Copenh)* 57(3): 344-350; 1979.

Retinoblastomas were diagnosed in 88 Swedish children (48 boys and 40 girls) during 1958-1971, giving an incidence of 1 case per 18,000 live births. The tumor was bilateral in 37.5% of the patients. A family history of retinoblastoma was recorded in only six cases, five of which were bilateral. All unilateral tumors were enucleated; in the bilateral cases, one eye was enucleated and the other was treated by local radiation therapy. Choroidal invasion was noted in 29% of the cases, and invasion of the optic nerve in 11%. The mortality was only 4.5%, which is considerably lower than the mortality rates reported in other Scandinavian countries. (17 refs)

- 79-5929 Menopausal Estrogen Therapy and Endometrial Cancer. (Swe) Bengtsson, L. P. (Kvinnokliniken, Lasarettet i Lund, Lund, Sweden). *Lakartidningen* 76(19): 1801-1802; 1979.

The effect of postmenopausal estrogen therapy on the incidence of endometrial cancer in Sweden was estimated from drug sales and from the estimated number of women using estrogens. Compared

with the US, the percentage of menopausal women receiving estrogen therapy is considerably lower and the duration of the treatment is substantially shorter, usually <3 yr. Based on the assumption that all menopausal women are treated with estrogens for at least 3 yr, the incidence of endometrial carcinoma would increase by an estimated 13/100,000, which means that the actual increase due to therapy is considerably lower than this estimate. Therefore, estrogen therapy at the lowest effective doses and for not >3 yr is justified for valid indications. (6 refs)

- 79-5930 Five-Year Survival and Causes of Treatment Failures in Patients with Lymphosarcoma. (Pol) Zuchowska-Vogelgesang, B. (Klinika Chemioterapii, Instytut Onkologii, ul. Garncarska 11, 31-115 Krakow, Poland); Pawlicki, M. *Nowotwory* 29(2): 115-119; 1979.

Transformation of lymphosarcoma into lymphocytic leukemia was seen in 64 patients within 5 yr of treatment (radiotherapy in all patients, and chemotherapy with Natulan, cyclophosphamide, vincristine, and vinblastine in 18). (16 refs)

- 79-5931 Leukemias at Lucknow. A Study of 200 Cases. (Eng) Kushwaha, M. R. (Lymphoma Leukemia Registry, Upgraded Dept. Pathology and Bacteriology, K. G. Medical Coll., Lucknow, India); Bagchi, M.; Mehrotra, R. M. *Indian J Cancer* 15(3): 28-34; 1978.

The frequency of leukemia and the relative incidence of different morphologic types of leukemia in Lucknow, India, were studied based on 392 cases. Chronic myeloid leukemia (CML) was the most prevalent type (56.1%), followed by acute myeloblastic leukemia (AML, 31.6%), acute lymphocytic leukemia (ALL, 8.1%), and chronic lymphocytic leukemia (CLL, 4.2%). The overall male:female ratio was 2:1, with the male predominance being most marked for CLL. Eighty percent of ALL patients were diagnosed in the first decade of life, 68% of AML patients were diagnosed in the third and fourth decades, and 73% of CLL patients were >40 yr of age. Most ALL and AML patients were urban dwellers, whereas most CLL and CML patients were rural dwellers. The incidence of leukemia in Lucknow appears to be increasing gradually. Hepatosplenomegaly, fever, bleeding episodes, and lymphadenopathy were common presenting symptoms, with the most common presenting symptom varying with morphologic type. Total WBC counts also varied with morphologic type, and the majority of AML and ALL cases had >20% blast cells in the peripheral blood. Anemia was found in the majority of the acute leukemias and in 45.6% of the CML cases. There was no definite relationship between platelet count and hemorrhagic tendency in any morphologic type. - 79-5932 Lymphomas and Occupational Benzene Exposure. (Eng) Vianna, N. J. (New York State Dept. Health,

Bureau Environmental Epidemiology and Occupational Health, Albany, NY); Polan, A. *Lancet* 1(8131): 1394-1395; 1979.

A comparison was made of the 1950-1969 mortality rates for reticulum cell sarcoma, lymphosarcoma, and Hodgkin's disease among male New York state residents (excluding New York City) aged ≥ 20 yr in 14 occupations with exposure to benzene and/or other coal tar fractions and among a nonexposed control group. Relative risks were calculated for the 14 occupations based on crude death rates; for the 7 occupations for which age distributions were available (representing 80% of the total study population), age-specific death rates for each lymphoma were calculated and applied to the age distributions. The Poisson distribution was used to evaluate the significance of the findings. The relative risks based on all 14 occupations were 1.6, 2.1, and 1.6 for reticulum cell sarcoma, lymphosarcoma, and Hodgkin's disease, respectively. Within the seven occupations for which age distributions were available, the observed number of deaths was significantly higher than the expected number for each type of lymphoma. Further analysis revealed that this excess was due entirely to those men 45 yr of age or older. These results are consistent with the possibility that chronic exposure to benzene and/or other coal tar derivatives may be important in the etiology of these tumors. (15 refs)

- 79-5933 Mycosis Fungoides: Epidemiologic Observations. (Eng) Greene, M. H. (Environmental Epidemiology Branch, Field Studies and Statistics Program, NCI, NIH, Landow Building, Room C307, Bethesda, MD 20205); Dalager, N. A.; Lamberg, S. I.; Argyropoulos, C. E.; Fraumeni, J. F. *Cancer Treat Rep* 63(4): 597-606; 1979.

An analysis of cases from a multihospital, pathologically verified clinical series and of deaths from US mortality statistics at the county level for 1950-1975 (excluding 1972) was made to obtain information on the etiology of mycosis fungoides (MF). Most of the cases (85%) were in men, 64% of whom were aged 45-69 yr. One hundred and eighteen of the 211 patients reported childhood eczema, asthma, hay fever, urticaria, and/or allergies to food, drugs, and/or contact allergens. Skin disease was reported in a first-degree relative of 56 patients, and a history of cancer was reported in a first-degree relative of 63 patients. Sixty-three patients reported at least one exposure to a hazardous chemical or material and 88% of the patients were employed in manufacturing or other industries. Ninety patients reported burning easily on sun exposure, and sun sensitivity, allergy, and previous skin infections seemed closely interrelated. During 1950-1975, there were 1,948 deaths attributed to MF, the av annual age-adjusted mortality rates being 0.53×10^6 for white men, 0.28×10^6 for white women, 0.84×10^6 for nonwhite men, and 0.54×10^6 for nonwhite women. The av age-adjusted mortality rates by race and sex revealed a generally upward trend over time. The mortality rate was highest among white men in the northeastern part of the country. The influence of occupational exposures was suggested by excessive mortality rates in counties where petroleum, rubber, primary and fabricated metal, machinery, and printing industries were located. - 79-5934 A Statistical Method for Testing Epidemiological Results as Applied to the Hanford Worker Population. (Eng) Brodsky, A. (P.O. 34471, W. Bethesda, MD 20034). *Health Phys* 36(5): 611-628; 1979.

A statistical method is presented for the evaluation of actual mor-

tality and longevity longitudinally over time and is preliminarily applied to previously reported data concerning the mortality experience of the Hanford worker population. A previous study had found increased radiation-produced cancer in this population. It is shown that when both employees and controls were selected from families with two or more offspring and comparisons were matched by age, sex, race and year of entry into employment, the gross mortality experience of persons employed at Hanford during 1943-1970 did not differ significantly from that of certain controls. In this method an approximate chi-square statistic for testing population subgroup comparisons is utilized, as is the cumulation of chi-squares for testing the overall result of a particular type of comparison. Some typical tables of the life-year and cumulative mortality data are presented and an explanation is given as to how the chi-square sample statistics were constructed, both for the individual subgroups and for the summed partitions of chi-square, to yield overall tests of each analysis. This method may be applicable for testing and screening in various kinds of health and population studies. (21 refs)

- 79-5935 Subacute Cadmium Intoxication in Jewelry Workers: An Evaluation of Diagnostic Procedures. (Eng) Baker, E. L. (Environmental Hazards Activity, Cancer and Birth Defects Div., Bureau Epidemiology, Center Disease Control, Atlanta, GA 30333); Peterson, W. A.; Holtz, J. L.; Coleman, C.; Landrigan, P. J. *Arch Environ Health* 34(3): 173-177; 1979.

An outbreak of cadmium intoxication in workers in a jewelry factory is reported. Blood Cd levels in exposed workers were higher than those in unexposed workers (0.93 vs $0.38 \mu\text{g}/100 \text{ ml}$), and a dose-response relationship was noted between blood Cd level and the prevalence of four symptoms (dyspnea, chest pain, dysuria, and dizziness). No significant renal or pulmonary dysfunction was noted. Symptoms ceased after a Cd-containing brazing alloy used in jewelry production was replaced, but urine Cd levels remained elevated in four workers 1 yr later. (16 refs)

- 79-5936 A Follow-Up Study of the Geographic Distribution of Selected Malignancies Among Kentucky Residents, 1969-1976. (Eng) Sims, W. L. (Office Student Affairs, Univ. Kentucky Medical Sch., Lexington, KY 40506); Marx, M. B.; Brooks, W. H. *J Natl Med Assoc* 71(7): 685; 1979.

A study of 533 brain tumors, 339 lung tumors, and 299 breast tumors in a contiguous six-county area of Kentucky was carried out to determine if a previous clustering of brain tumors with a rate 3.37 times the rate in the rest of the state still existed. No significant difference in incidence by age, sex, or race was demonstrated between cases assignable to the six-county area and those from the entire state. (2 refs)

- 79-5937 Metastatic Brain Tumors in Two Predominantly Black Hospitals: A Statistical Analysis. (Eng) Fan, K. J. (Dept. Pathology, Howard Univ., Coll. Medicine, 520 W St. NW, Washington, DC 20059); Kovi, J. *J Natl Med Assoc* 71(7): 671-673; 1979.

A retrospective statistical analysis was done on metastatic brain tumors collected from two predominantly black hospitals in Washington, DC. A composite African series of metastatic brain tumors was also constructed for comparison. The results indicate

that bronchogenic carcinoma is the predominant metastatic brain tumor (45.2%) among the American blacks and chorio-epithelioma, the most common (20.0%) among the African blacks. In comparing these two series, much dissimilarity in the pattern of tumor distribution between these two genetically related ethnic groups suggests an important environmental role in the genesis of metastatic brain tumors. The present study also reveals a relatively high proportional frequency of prostatic carcinoma among metastatic brain tumors in blacks (3.8 percent in Washington, DC and 2.1 percent in Africa). (23 refs)

- 79-5938 Brain Tumors in Children Exposed to Barbiturates (2 Letters to Editor).** (Eng) Annegers, J. F. (Dept. Medical Statistics and Epidemiology, Mayo Clinic, Rochester, MN 55901); Kurland, L. T.; Hauser, W. A.; Gold, E. B.; Gordis, L.; Tonascia, J. A.; Szklo, M. *J Natl Cancer Inst* 63(1): 3-4; 1979.

A previous observation that children with brain tumors have a threefold increase in prior barbiturate exposure compared with that in a control population is criticized methodologically. Reasons for selecting barbiturates as a variable for the study are not given, and the types of barbiturates, duration of exposure to and the histologic types, sites, and ages at onset of the neoplasms are not fully described. The confidence intervals are large and the basic comparisons among the data are not statistically significant, which deny support for the suggested association. New data concerning barbiturate exposure and subsequent brain tumors in three cohorts exposed to anticonvulsants either in utero (1st trimester), in childhood for long periods, or as epileptic therapy are presented to further illustrate the criticisms. In a rebuttal, the authors of the original report respond to the methodological criticisms. They also state that the possibility of confounding by associated variables such as head trauma, CNS anomalies, or epilepsy may be minimal. Although the findings were only suggestive and, at most, only a small proportion of brain tumors may be attributed to barbiturate exposure, they are of sufficient interest to warrant further study in this area. (1 ref)

- 79-5939 Mortality in Aluminum Reduction Plant Workers.** (Eng) Milham, S. (Washington State Dept. Social and Health Services, Olympia, WA 98504). *J Occup Med* 21(7): 475-480; 1979.

A historical prospective (cohort) study of workers at a north-western US prebake-type aluminum reduction plant revealed a low standardized mortality ratio (SMR) for all causes of death (86), but excess deaths from lung cancer (SMR 117), pancreatic cancer (180), lymphatic and hematopoietic cancers (184), fatal benign brain tumors (391), and pulmonary emphysema (204). Analysis of mortality by job-exposure category, duration of employment, and latency suggested that some of the lymphatic and hematopoietic cancers (especially malignant lymphoma), lung cancers, and pulmonary emphysemas were of occupational origin in this population. (16 refs)

- 79-5940 Lung Cancer in Young Women.** (Eng) Jick, H. (Boston Collaborative Drug Surveillance Program, 400 Totten Pond Road, Waltham, MA 02154); Porter, J.; Morrison, A. S.; Rothman, K. J. *Arch Intern Med* 139(7): 745-746; 1979.

The cigarette smoking histories of 31 women below age 50 yr who had a diagnosis of lung cancer on hospital discharge and of 124 women below age 50 yr who had been hospitalized for other conditions were compared. Of the women with lung cancer, 28 were current or former cigarette smokers; 72 of the comparison women were smokers. The relative risk estimate for lung cancer among smokers, compared with that among nonsmokers, was 6.7, with 90% confidence limits of 4.0 and 11. Lung cancer risk increased with the amount of cigarettes that the women had smoked. The smokers with lung cancer had been smoking for longer periods than the smokers with other conditions. Assuming that the association is causal, cigarette smoking was responsible for about 77% of the cases of lung cancer found among young women in this survey. (15 refs)

- 79-5941 Relation of Steroids to Liver Oncogenesis.** (Eng) Christopherson, W. M. (Health Sciences Center, Univ. Louisville Sch. Medicine, Louisville, KY); Mays, E. T. *J Toxicol Environ Health* 5(2/3): 207-230; 1979.

Experience with pathological material from 150 women with liver tumors is reviewed. The average age of the women was 30 yr. Approx 85% had taken contraceptive steroids, most for >3 yr: 18% had taken pills containing ethinylestradiol, 64% pills containing mestranol, and 18% pills containing both preparations. The most common presenting symptom was pain; 20% presented with hemoperitoneum. The features of liver cell adenoma and focal nodular hyperplasia are sufficiently different that the vast majority of the benign tumors can be easily subclassified. Although most occurred in women ingesting steroids, the wide usage of oral contraceptives makes it difficult to prove a causative role. Nineteen patients had malignant tumors (hepatomas) and, to date, 14 have died of their disease. Since hepatomas are much more common than benign liver tumors, one must be even more circumspect in indicating steroids in their causation. None of the women had cirrhosis, whereas cirrhosis is a very common precedent lesion in the general population. Further investigation of estrogens and primary liver carcinoma is needed. (40 refs)

- 79-5942 Survey of Primary Liver Tumors and Oral Contraceptive Use.** (Eng) Vana, J. (Dept. Epidemiology, Roswell Park Memorial Inst., Buffalo, NY); Murphy, G. P.; Aronoff, B. L.; Baker, H. W. *J Toxicol Environ Health* 5(2/3): 255-273; 1979.

Survey data of the American College of Surgeons on 378 female and 165 male cases of primary liver tumor reported by 477 US hospitals during 1970-1975 are presented. In men, 91.5% of the tumors were malignant, confirming the rarity of benign liver tumors in men. Among women, 43.9% were malignant and 56.1% were benign. Of the 212 benign tumors, 96 were hepatic cell adenomas and 58 were focal nodular hyperplasias. A positive history of oral contraceptive use was found in nearly half of all tumors, 65% of benign tumors, 74% of hepatic cell adenomas, and 74% of focal nodular hyperplasias. High frequencies of benign tumors were observed in the age group 20-30 yr. More than 80% of the tumors in this age group were found in oral contraceptive users. Symptomatology was more severe among users. No case of ip bleeding was observed in nonusers. The findings confirm the suggested association between use of oral contraceptives and hepatic cell adenomas and focal nodular hyperplasias. (38 refs)

- 79-5943 Liver Cancer in the Chinese. (Ger) Wellmann, K. F. (Dept. Pathology, Beekman Downtown Hosp., 170 William St., New York, NY 10038); Gerstmann, K. E. *Disch Med Wochenschr* 104(26): 949-954; 1979.

The incidence of liver cancer among the Chinese people and its possible causes are reviewed, along with observations of patients from the Chinese section of New York City. In the US, the risk of dying of liver cancer was calculated to be 9.66 for Chinese men, 1.0 for white men, and approx 2 for black men. The risk for Chinese women living in the US was 4.31. These results are based on data collected from 1950 to 1969. Among a series of autopsies in which 15.5% of the patients were Chinese, 60% of the liver cancers were found in Chinese patients. Several studies show that the incidence of liver cancer is higher in Chinese born in China than in those born elsewhere. Thus, an environmental factor that exerts its influence early in life is suspected. Parasitic or virus infection, nutritional deficiency in childhood, and high consumption of a carcinogen (eg, aflatoxin) have been suggested. The association between liver cirrhosis (LCR) and carcinoma is closer for the Chinese people than for people of other races. In New York, 33.3% of Chinese patients with LCR had liver carcinoma, vs 4.4% of non-Chinese LCR patients. The incidence of LCR found at autopsy was 14.4% in Chinese vs 13.2% in non-Chinese subjects. The risk of liver cancer in Chinese that have had a hepatitis B infection was estimated to be 10 times that for Chinese not so infected. This increase in risk seems to be greater than that for other races. Hepatitis is very common in parts of China. It is suggested that the incidence of liver cancer might be decreased by the prevention of hepatitis. (68 refs)

- 79-5944 Malignant Neoplasms in Long-Term Hemodialysis Patients. (Eng) Fayemi, A. O. (Holy Name Hosp., 718 Teaneck Road, Teaneck, NJ 07666); Ali, M. *J Med Soc NJ* 76(7): 497-500; 1979.

The incidence of malignant neoplasms is increased in patients with chronic renal insufficiency maintained on long-term intermittent hemodialysis. A clinical and pathological study was made of 10 such patients encountered in a hemodialysis unit over the period 1969 through 1977. These patients developed 12 malignancies that were predominantly epithelial in origin: carcinomas of the thyroid (2), liver (2), colon (2), lung (1), stomach (1), kidney (1), prostate (1), and pancreas (1), and a glioblastoma multiforme. In five patients, death was attributable directly to the neoplasms. Numerous abnormalities of cellular and humoral immunity occur in uremic (and hemodialysis) patients, and they may contribute to the development of malignant tumors. (31 refs)

- 79-5945 Geographic Patterns of Renal Cancer in the United States. (Eng) Blot, W. J. (Environmental Epidemiology Branch, Div. Cancer Cause and Prevention, NCI, NIH, Bethesda, MD 20205); Fraumeni, J. F. *J Natl Cancer Inst* 63(2): 363-366; 1979.

Mapping of the geographic distribution of renal cancer mortality for groupings of US counties revealed clustering of elevated rates among white men and women in the upper north-central part of the country. Throughout the US, mortality increased with urbanization for men only, whereas rates for both sexes showed positive correlations with socioeconomic status. The major correlate of the cancer rates was ethnicity. Mortality was elevated in counties with high percentages of residents of German, Scandina-

vian, and, especially, Russian descent. Ethnic susceptibility appears to account, at least partly, for the regional clustering of kidney cancer and may provide leads to environmental determinants. (19 refs)

- 79-5946 Trends in the Anatomic Distribution of Colorectal Cancer (Letter to Editor). (Eng) Welch, J. P. (Dept. Surgery, Univ. Connecticut Health Center, Farmington, CT). *Conn Med* 43(7): 457-458; 1979.

A retrospective examination of the Hartford Hospital Tumor Registry records from 1935 to 1977, revealed a persistent increase in the incidence of colorectal cancer during each succeeding decade and an increase in the incidence of cancers of the cecum and ascending colon. There was a simultaneous decrease in rectal cancer incidence. Changes in the distribution of colorectal cancer reflect, in part, the enhanced detection of more proximal tumors using colonoscopy and air-contrast barium studies and the effective removal of polyps in the rectum and lower sigmoid colon. (7 refs)

- 79-5947 Laterality of Breast Cancer in Families. (Eng) King, M. C. (Dept. Epidemiology and International Health, Univ. California, San Francisco, CA 94143); Lynch, H. T.; Selvin, S. *Am J Epidemiol* 110(1): 88-98; 1979.

A new method for analyzing concordance for a binary variable in extended pedigrees was used to study tumor laterality in 15 extended families with 63 members affected by breast cancer. Concordance and discordance measures were almost equal among these families, and there was no significant concordance for tumor laterality. However, among the Danish families of a 1948 study, concordance for tumor laterality was more than twice discordance for laterality for related breast cancer patients ($p = 0.006$). Another earlier study demonstrated significant concordance for laterality ($p < 0.05$) among twins, and the 1948 study demonstrated a nonsignificantly high concordance among siblings. The present study and a third earlier study showed a weak tendency toward discordance among sisters. Three studies indicated a tendency toward concordance for tumor laterality among parent-child pairs, but the trend was significant only in the 1948 study. The pooled data from all three studies showed a highly significant concordance among the 67 parent-child pairs ($p < 0.005$). (21 refs)

- 79-5948 Cancer of the Corpus Uteri: Increasing Incidence in the United States, 1970-1975. (Eng) Walker, A. M. (Boston Collaborative Drug Surveillance Program, Boston Univ. Medical Center, Waltham, MA); Jick, H. *Am J Epidemiol* 110(1): 47-51; 1979.

Regional and temporal variations in the incidence of cancer of the corpus uteri in the US during 1970-1975 were studied. During this period, rates for women aged 50-59 yr increased 81%, from 72 to 130 cases per 100,000 woman-yr at risk (WYAR). Rates for women aged 60-69 yr rose 57%, from 82 to 129/100,000 WYAR, and rates for women aged ≥ 70 yr increased 53%, from 45 to 53/100,000 WYAR. Despite considerable variations in incidence during the study period, the rate for women aged 40-49 yr was 31/100,000 WYAR at the beginning and end of the period. Regional variations were greatest among women aged ≥ 50 yr, especially those aged 60-69 yr. The peak incidence in the West (190/100,000) was three times that in the Northeast, which had the lowest incidence for

women aged 60-69 yr. The age of peak incidence tended to be higher in the areas of higher risk. All rates were corrected for the numbers of women in each region and age group with intact uteri. (16 refs)

- 79-5949 Endometrial Cancer in Relation to Patterns of Menopausal Estrogen Use. (Eng) Weiss, N. S. (Dept. Epidemiology, Univ. Washington, SC-36, Seattle, WA 98195); Szekely, D. R.; English, D. R.; Schweid, A. I. *JAMA* 242(3): 261-264; 1979.

The relationship between endometrial cancer and pattern of estrogen use (dose, duration, presence of an intermittent progestogen, etc) was investigated in female residents of King County, Washington, in whom endometrial cancer developed between January 1975 and April 1976. These women were interviewed concerning prior use of menopausal estrogens, and their responses were compared with those of a random sample of women from the same population. Among current estrogen users, endometrial cancer risk was strongly related to duration of use; although only a minimal elevation of risk was present during the first 2 yr, there was a rapid rise to a 20-fold excess after about 10-15 yr. Cessation of estrogen use led to a decline in the incidence of endometrial cancer within several years, but the risk remained higher than that in nonusers through the first decade after administration of the drug was stopped. Risk was elevated whether or not the regimen was cyclic and whether conjugated or other types of estrogens had been used. Dosages of <0.625 mg/day of conjugated estrogens produced a smaller increase in risk than did other dosages. (11 refs)

- 79-5950 Use of Permanent Hair Dyes and Cancer among Registered Nurses. (Eng) Hennekens, C. H. (180 Longwood Ave., Boston, MA 02115); Rosner, B.; Belanger, C.; Speizer, F. E.; Bain, C. J.; Peto, R. *Lancet* 1(8131): 1390-1393; 1979.

A retrospective evaluation was made of the possible association between the use of permanent hair dyes and cancer. The assessment also followed for any confounding effects of cigarette smoking. A 1976 survey of 120,557 married, female, registered US nurses aged 30-55 yr showed that 38,459 had at some time used hair dyes and 3,548 had had cancer. For all cancers combined, the risk ratio (RR) for the development of cancer among women who had used hair dyes at any time, compared with those who had never used them, was 1.10 ($p = 0.02$). When cancers were subdivided by anatomical site into 16 main groups, only those of the cervix uteri ($RR = 1.44$, $p < 0.001$) and those of the vagina and vulva ($RR = 2.58$, $p = 0.02$) showed statistically significant associations with the use of permanent hair dyes. Both these associations were reduced but remained significant after standardization for cigarette smoking, and neither showed increases in risk of cancer with increasing years since first use of hair dyes. Women who had used permanent dyes ≥ 21 yr before the onset of cancer had a significant increase in risk for all sites combined ($RR = 1.38$, $p = 0.02$), compared with never users. This increase was primarily due to an excess number of observed to expected cases of breast cancer (24 vs 16.3). However, among those who had first used dye 16-20 yr before the diagnosis of breast cancer, there was an almost equal deficit in number of cancers at this site (16 observed vs 25.1 expected). The present evidence does not indicate that any material risk of cancer is likely to have occurred during the initial 20 yr following the first use of permanent hair dyes. (12 refs)

- 79-5951 Vasectomy and Cancer of the Cervix (Letter to Editor). (Eng) Swan, S. H. (Kaiser-Permanente Medical Center, Walnut Creek, CA 94596); Brown, W. L. *N Engl J Med* 301(1): 46; 1979.

The relative risk of cervical cancer in women with sexual partners without vasectomies was found to be 4.29 times that among women who had partners with vasectomies ($p < 0.05$). (2 refs)

- 79-5952 Epidemiology of Cancer of the Cervix in Buffalo, New York. (Eng) Graham, S. (Dept. Sociology, State Univ. New York at Buffalo, Buffalo, NY 14261); Schotz, W. *J Natl Cancer Inst* 63(1): 23-27; 1979.

A study was made to determine whether cervical cancer patients from Buffalo and Kenmore, New York, differed from a random sample of women from the same communities on a variety of parameters associated with marital and reproductive history. A comparison of the 285 patients and 1,620 controls showed that patients were more likely than controls to have been black and non-Jewish, to have married young, to have had more than one husband, and to have been young at the time of their first pregnancy. In addition, they were more likely to have frequently used a vaginal douche and to have used it over many years. As the frequency of douching increased, so did the risk of cervical cancer. (9 refs)

- 79-5953 Discussion of Cytological Studies Performed in 1976. Conclusions. (Spa) Marhuenda Sendra, F. (No affiliation given); Medina Diez, J. M. *Rev Sanid Hig Publica (Madr)* 52(9/10): 1115-1123; 1978.

The results of 2,097 consecutive cervical and vaginal cytological examinations performed in 1976 are presented. Of 2,097 patients, 1,796 were urban and 301 provincial; 1,266 presented voluntarily, and 831 were referred. Most of the patients (1,301/2,097) belonged to the 31- to 50-yr age group. Complaints included leukorrhea (524), pain (363), and menstruation disorders or metrorrhagia (203). Six adenocarcinomas, 5 squamous cell carcinomas, 12 serious dysplasias, 142 mild dysplasias, 82 cases of mycosis, and 183 cases of trichomoniasis were diagnosed. (no refs)

- 79-5954 Mumps Virus and Ovarian Cancer. (Eng) Golan, A. (Dept. Obstetrics and Gynaecology, Baragwanath Hosp., Johannesburg, S. Africa); Joosting, A. C.; Orchard, M. E. *S Afr Med J* 56(1): 18-20; 1979.

The relationship between cancer of the ovary and mumps-neutralizing antibodies was investigated with the use of 34 ovarian carcinoma patients and controls matched for age, sex, and racial origin. Previous mumps infection was determined by interview, by complement fixation tests, and by estimations of neutralizing antibody titer. No significant differences between the two groups were found with any of the three methods used to estimate previous exposure to mumps virus. Therefore, this study did not confirm previous hypotheses that mumps infection confers a significant degree of protection against the development of ovarian cancer. A relatively small proportion of cases could possibly be due to a lack of such protection, but in this study the max possible is 30% at a fiducial limit of 5%. (19 refs)

- 79-5955 The Epidemiology of Ovarian Carcinoma. (Ger) Wolnik, L. (Universitäts-Frauenklinik, Pilgrimstein 3, D-3350 Marburg 1, W. Germany); Bauer, H. *Onkologie* 2(2): 96-101; 1979.

A study of 190 women with ovarian cancer treated during 1962-1976 showed that this group contained a high percentage of childless women and women with more than four children. A high social standing, blood group A, obesity, diabetes, high blood pressure, uterine polyps, a previous appendectomy or laparotomy for other causes, and several relatives with cancer were also found to be risk factors. (50 refs)

- 79-5956 Breast Cancer Incidence: Geographical Correlations in Finland. (Eng) Hakama, M. (Finnish Cancer Registry, Liisankatu 21 B, 00170 Helsinki 17, Finland); Soini, I.; Kuosma, E.; Lehtonen, M.; Aromaa, A. *Int J Epidemiol* 8(1): 33-40; 1979.

An attempt was made to determine whether geographical differences in fertility factors and in standard of living in Finland account for the observed geographical differences in breast cancer incidence rates. Breast cancer risk was found to be associated with fertility and taxable income but not with the size of the woman. Trends in risk factors indicate that the rapid increase in the incidence of breast cancer is likely to continue. It is concluded that factors that are reflected by the standard of living and fertility might act independently and not through the nutritional status, for which the size of the woman is an operational indicator. - 79-5957 An Epidemiological Study of Oral Contraceptives and Breast Cancer. (Eng) Vessey, M. P. (Univ. Dept. Social and Community Medicine, Oxford OX1 3QN, England); Doll, R.; Jones, K.; McPherson, K.; Yeates, D. *Br Med J* 1(6180): 1757-1758; 1979.

From 1968 to 1977, 707 women aged 16-50 yr with newly diagnosed breast cancer and 707 matched controls were interviewed at eight teaching hospitals in London and Oxford about their use of oral contraceptives (OC). Eighty-six of the breast cancer patients were matched with controls with gallbladder disease; these subjects were omitted from the main analyses, which thus related to 621 case-control pairs. A few statistically significant differences in OC use were found between the breast cancer and control groups, but the data were subdivided in many ways, so that some "significant" differences would have been expected to occur by chance. The only subgroup in which the evidence for a positive association between OC use and breast cancer was convincing comprised women aged 46-50 yr, but trends in those aged 41-45 were by and large in the opposite direction, and the results of combined analyses gave no cause for concern. Information on clinical stage was available for 487 breast cancer patients treated before the end of 1975. Those who had never used OC had appreciably more advanced tumors at presentation than those who had been using OC during the year before detection of the lump; while past users of OC occupied an intermediate position. This difference in staging was reflected in the pattern of survival. OC may have had a beneficial effect on tumor growth and spread, although diagnostic bias could not be definitely excluded. - 79-5958 Results of Rectoscopic Studies of Unselected Patients. (Ger) Veres, R. (Klinik Hochstaußen, Postfach 13, D-

8232 Bayerisch Gmain, W. Germany); Berghoff, A. *Med Klin* 74(12): 449-452; 1979.

Unsuspected rectal carcinomas were found in 7/1,665 unselected patients (>45 yr old) with common internal disorders that were studied rectoscopically. Only two of these tumors were palpable. At least 1 polyp was found in 304/1,665 patients; 126 of these had the histological criteria of premalignancy. Rectoscopy is recommended for the regular screening of patients at internal medicine clinics. (13 refs)

- 79-5959 Etiology of Human Liver Cancer: Controlled Prospective Study in Liver Cirrhosis. (Eng) Lehmann, F. G. (Dept. Medicine, Univ. Marburg, Marburg/Lahn, W. Germany); Wegener, T. *J Toxicol Environ Health* 5(2/3): 281-299; 1979.

The incidence of primary hepatocellular carcinoma (PHCC) was investigated in a 77-mo prospective study of 403 clinically unselected patients derived from a homogeneous population by serial determination of α_1 -fetoprotein (AFP) with the use of radioimmunoassay. The diagnosis of liver cirrhosis was proved in 90% by laparoscopy and/or histology and/or autopsy. The incidence of PHCC in liver cirrhosis in the clinically studied patients was 4.47%, significantly lower than that in the autopsy material (11.03%; $p \leq 0.025$). In the follow-up study, all patients with increasing AFP concentrations exhibited a PHCC. A transitory rise of AFP (>50 nanograms/ml) was observed in 15.1% of patients with liver cirrhosis without PHCC. In contrast to the results of animal experiments, this transitory rise of AFP was not followed by malignant transformation of the cirrhotic tissue. Posthepatic liver cirrhosis was observed in 21.57%, postalcoholic liver cirrhosis in 42.93%, and cryptogenic liver cirrhosis in 27.30%. Liver cirrhosis of other etiology occurred in 8.19%. The incidences of PHCC in these four groups were 4.94%, 4.62%, 5.45%, and 0%, respectively. These differences are not statistically significant, although in absolute figures, postalcoholic liver cirrhosis was the main cause of PHCC in this sample from West Germany. Hepatitis B surface antigen (HBsAg)-positive liver cirrhosis was more often associated with PHCC than HBsAg-negative liver cirrhosis (6.58% vs 3.96%); this difference also is not statistically significant. Observations of larger groups of patients may show a higher risk of developing PHCC in those with a combination of alcohol abuse and HBs antigenemia and/or acute hepatitis in their history. Patients without these two risk factors had a 2.61% incidence of PHCC; those with one risk factor, 5.77%; and those with both risk factors, 10.71%. (55 refs)

- 79-5960 Epidemiological Study of Carcinoma of Liver in the Dodoma Region of Tanzania. (Eng) Hiza, P. R. (Muhimbili Medical Centre, Univ. Dar es Salaam, P.O. Box 20693, Dar es Salaam, Tanzania). *J Natl Med Assoc* 71(6): 585-587; 1979.

Because primary hepatocellular carcinoma (PHC) is common in Africa and because the disease probably has an environmental etiology, a study was undertaken in Dodoma, Tanzania, to obtain baseline data on PHC prior to the improvement in hygiene and diet that are likely to occur. These baseline data may help pinpoint the causative factors in PHC. Of the 939 patients diagnosed as having cancer at any of the four Dodoma regional hospitals, 27% had PHC, a high incidence by all standards. Of 141 patients interviewed at these hospitals, 88% consumed ground nuts either daily

or weekly, and 50% of these respondents ate the nuts after storage. There were 124 regular consumers of ground nuts and 17 non- or occasional consumers. In addition, 49% of the consumers but only 18% of the non- or occasional consumers had a positive history of jaundice, a finding that is statistically significant. The significance of these findings in relation to PHC is not clear. It appears that regular ground nut consumption affects the liver so as to make it more susceptible to hepatitis. The effect may be due to hepatotoxins in the nuts that damage the liver and make it more susceptible to hepatitis B virus infection. (3 refs)

- 79-5961 Carcinoma of the Esophagus. (Eng) Ajao, O. G. (Dept. Surgery, Univ. Ibadan and Univ. Coll. Hosp., Ibadan, Nigeria); Solanke, T. F. *J Natl Med Assoc* 71(7): 703-705; 1979.

Carcinoma of the esophagus, previously thought to be rare in West Africa, is now known to be relatively common in Ibadan. In a 39-mo period, extending from January 1975 to March 1978, 30 cases of esophageal carcinoma were seen on the surgical service of one hospital. Males were affected more than females (2.3:1), and the highest incidence was found in the sixth and seventh decades of life. Of the 30 patients, 23 belonged to the low and 7 to the low-middle socioeconomic classes. The predominant histological type was squamous cell carcinoma (90%), with the remainder being adenocarcinoma; the most common site was the lower third of the esophagus (51.85%), followed by the midthoracic esophagus (29.6%). Surgical resection is recommended when feasible, even as a palliative measure. (12 refs)

- 79-5962 Cohort Analysis of Lung Cancer in the Netherlands. (Eng) Van Der Hoff, N. M. (Peeskesweg 3, Beek Gem., Bergh, Netherlands). *Int J Epidemiol* 8(1): 41-47; 1979.

A mathematical method was used to analyze lung cancer mortality in the Netherlands from 1963 to 1974. A multiplicative model was fitted to a two-dimensional table of age- and cohort-specific rates. Apart from small corrections, age-specific lung cancer mortality rates could be expressed as the product of a cohort (generation) factor and an age factor. The cohort factors increased until the 1930 birth cohort, after which there was a rapid decline. The age-risk factors increased gradually with age. Age-specific incidence curves for past and future years will follow the curve of the age-risk factors, provided that the cohort-risk factors do not change. The method can be applied to other chronic diseases. (8 refs)

- 79-5963 Relationship Between Clinical Findings and Histology of Primary Lung Cancer. (Jpn) Kobara, Y. (Second Dept. Medicine, Chest Disease Res. Inst., Kyoto Univ., Kyoto, Japan); Sato, A.; Matsui, Y.; Imai, H.; Honda, K.; Oshima, S. *Bull Chest Dis Res Inst Kyoto Univ* 12(1/2): 17-27; 1979.

The relationship between cigarette smoking and lung cancer was confirmed in a study of 728 patients (578 men, 150 women). There were 290 men and 39 women with epidermoid carcinoma, 146 and 76 with adenocarcinoma, 137 and 27 with undifferentiated carcinoma, and 5 and 8 with alveolar cell carcinoma, respectively. Among the cigarette smokers (342 men, 64 women), 173 men and 15 women had epidermoid carcinoma, 82 and 31 had adenocarcinoma, and 87 and 18 had undifferentiated carcinoma. The smokers were classified according to the Brinkman Index (BI =

number of cigarettes smoked/day x total years smoking). A person with a BI of >400 is considered a heavy smoker. There was an especially large number of heavy smokers with epidermoid carcinoma and undifferentiated carcinoma and a lower number of heavy smokers with adenocarcinoma. A BI of >600 was found in 132/173 men with epidermoid carcinoma and 71/87 men with undifferentiated carcinoma. The occurrence of adenocarcinoma was significantly higher among nonsmokers than smokers, and there were significantly fewer women smokers than men. There was a correlation between cigarette smoking and the incidence of epidermoid and undifferentiated carcinoma. (17 refs)

- 79-5964 Cancer in the Aged: An Autopsy Study of 940 Cancer Patients. (Eng) Ishii, T. (Dept. Pathology, Keio Univ. Sch. Medicine, 35 Shinanomachi, Shinjuku-Ku, Tokyo 160, Japan); Maeda, K.; Nakamura, K.; Hosoda, Y. *J Am Geriatr Soc* 27(7): 307-313; 1979.

Among 1,366 patients aged 65 or older autopsied between 1955 and 1977, 940 were found to have one or more cancers (total, 1,030 cancers). The prevalence rate for overall cancer declined after age 85 in men and after age 75 in women. The chief sites of major cancers were the stomach, lung, esophagus, liver, and pancreas, in that order. Incidental cancers (chiefly of the prostate, thyroid, and colon) were found more often in patients >80 yr old. For multiple primary cancers, the prevalence rate was relatively constant until the age of 70, when it rose to a peak in the 80-84 age group before declining to the original level. (26 refs)

- 79-5965 Diet and Cancer. (Eng) Hirayama, T. (Epidemiology Div., Natl. Cancer Center Res. Inst., Tokyo, Japan). *Nutr Cancer* 1(3): 67-81; 1979.

Data from a series of Japanese studies concerning the effect of diet on cancers of the lung, esophagus, stomach, colon, breast, and cervix are reviewed. The risk of lung cancer in smokers and nonsmokers was reduced by consumption of green-yellow vegetables (GYV), and among ex-smokers, reduction in lung cancer risk with time after cessation of smoking was greater among those who consumed GYV daily than among others. Vitamin A must be the most important factor in any protective effect of GYV, followed by vitamin C. GYV consumption had a similar, but weaker effect on colon, stomach, and prostate cancers. The risk of esophageal cancer was increased in those who smoked and consumed alcohol, the risk increasing with the alcohol content of the beverage consumed. The risk of esophageal cancer was also increased by the combined intake of bracken fern and hot tea gruel. Stomach cancer was lowest in persons consuming two glasses of milk daily, and the amount of fiber consumed was negatively correlated with colon cancer mortality. Daily meat intake had no effect on colon cancer risk, but daily meat consumption was associated with increased breast and pancreatic cancer risks. Breast cancer mortality was positively correlated ($r = 0.842$) with daily fat intake. The risk of cervical cancer was negatively correlated ($r = -0.855$) with vitamin A intake. (17 refs)

- 79-5966 Gastrointestinal Disorders. Patients seen During 1977 in an Internal Medicine Clinic Oriented Toward Hepatogastroenterology. (Fre) Bockel, R. (Service de medecine interne III, gastro-enterologie, Clinique medicale B, C.H.U. Strasbourg, France); Schneider, R.; Saada, K.; Doffoel, M.; Girard, M.; Coumaros, D. *Arch Mal Prof* 40(1/2): 216-221; 1979.

Clinical findings were compared for 444 immigrants and 984 native French subjects with gastrointestinal disorders seen in a hospital and outpatient clinic during 1977. No neoplasms were diagnosed in the immigrants, but 34 neoplasms (4 esophageal, 5 gastric, 11 hepatic, 4 pancreatic, and 10 colorectal tumors) were found in the native French patients. (no refs)

79-5967 Incidence of Gastrointestinal Cancers in a Well-defined French Population. Survey of Registration Data in the Cote d'Or for 1976-1977. (Fre) Faivre, J. (Registre des cancers digestifs, Faculte de Medecine, 7 bd Jeanne-d'Arc, 21033 Dijon Cedex, France); Keppling, C.; Martin, F.; Cabanne, F.; Michiels, R.; Dusserre, P. *Rev Epidemiol Sante Publique* 27(1): 41-49; 1979.

The results of a systematic registration of the mortality and morbidity from gastrointestinal (GI) cancer in the Cote-d'Or, France (population, 455,727), during 1976 and 1977 are reported. In this 2-yr period, there were 692 deaths from GI cancer, and 913 new cases were reported. The site most likely to be involved was the colorectal area (246 deaths and 444 new cases), followed by the stomach (148 deaths and 174 new cases); the site least likely to be involved was the small intestine (3 deaths and 7 new cases). The incidence of cancer of the esophagus and intestine rose sharply after age 45; that of cancer of the stomach, liver, and pancreas rose sharply after the age of 50. Cancers of the esophagus were most likely to be squamous cell carcinomas (71%) whereas cancers in other GI sites were almost always adenocarcinomas. The mortality rate 1 yr after registration was 80% for cancers of the esophagus, 71% for primary cancers of the liver, 67% for cancers of the stomach and the pancreas, 45% for cancers of the colon, and 32% for cancers of the rectum. (8 refs)

79-5968 Changes in Mortality Due to Carcinoma of the Stomach in France Between 1954 and 1974. (Fre) Brunet, M. (Division de la Recherche Medico-Sociale, INSERM, Section Cancer, 44 chemin de Ronde, 78110 Le Vesinet, France); Berlie, J.; Janin, M. L.; Zimmermann, B.; Hucher, M.; Ducourneau, R. *Nouv Presse Med* 8(21): 1743-1744; 1979.

Changes in mortality due to carcinoma of the stomach in France between 1954 and 1974 were studied on the basis of probable levels standardized for the French population in 1968. There was a marked decline in mortality for both sexes. In men, the 1954 level was 54.8/100,000, and the decrease was of the order of 1.35 deaths/100,000/yr, an annual decrease of 3.21%. This phenomenon was more marked during the second period (1965-1974), than during the first period (1954-1963), with the decreases amounting to 3.88% and 2.38%, respectively. In women, the initial mortality rate was 31.25/100,000, and the annual decrease was 3.49%. The fall was 3.09% for the first 10-yr period and 4.80% during the second period. Thus, in France, as in many other countries, there has been a marked decrease in mortality due to carcinoma of the stomach. (no refs)

79-5969 Mortality due to Bladder Cancer in France, 1952-1976. Trends and Increase, Particularly in the South of France. (Fre) Berlie, J. (Centre Rene Huguenin, 5 rue Gaston-Latouche, F 92210 Saint-Cloud, France); Janin, M. L.; Hucher, M.; Gest, J.; Brunet, M. *Bull Cancer (Paris)* 66(3): 317-326; 1979.

Data on bladder cancer mortality in France during 1952-1976 were analyzed statistically to determine whether there were any relationships between this mortality and sex, age, or geography. Among men, the mortality rate increased from 3.8/100,000 in 1952 to 9.2/100,000 in 1976; the corresponding figures for women were 2.06/100,000 and 3.30/100,000. The annual increase was 2.65% among men and 1.34% among women, so that in 1976, the age-adjusted mortality rate was 11.35/100,000 men and 3.20/100,000 women. When mortality was analyzed by birth cohorts, absolute levels for the age group 70-79 yr increased from 41.1 for the population born before 1900 to 47.5 for the following generation. Computerized mapping of the geographical distribution of bladder cancer showed a significant predominance in the south of France and a highly significant correlation with the geographical distribution of lung and gallbladder cancer mortality in France. (10 refs)

79-5970 Epidemiological Study of 314 Cases of Cancer of the Bladder in the Administrative Department of Bas-Rhin, France. (Eng) Bollack, C. (Service de Chirurgie Urologique, C.H.U., Strasbourg, France); Poyot, G. *Urol Res* 7(2): 127-130; 1979.

The geographical distribution of 314 cases of bladder cancer among eight districts of the Department of Bas-Rhin in France was studied. Considerable variations in morbidity were observed, with an urban predominance possibly due to environmental factors. The av morbidity in two districts was 7.3 cases/100,000 residents, which was similar to the av for the Department as a whole. In two other districts, the av morbidities were 10 and 8.5 cases/100,000 residents, respectively, and in four districts the av was between 5.9 and 6.1 cases/100,000 residents. Among 180 patients studied more extensively, nine (5%) had second tumors diagnosed before, at the same time as, or shortly after the diagnosis of bladder cancer. Of five such patients with second tumors of the lung, pharynx, or mouth, five were heavy smokers. (11 refs)

79-5971 Cancers of the Ethmoid in Woodworkers. (Fre) Haguenaer, J. P. (Institut universitaire de medecine du travail de Lyon, Lyon, France); Bourret, J.; Duclos, J. C.; Dubreuil, C.; Arnould, G. *Arch Mal Prof* 40(1/2): 422-423; 1979.

Among a series of 55 patients with adenocarcinomas or other malignant tumors of the ethmoid diagnosed since 1972, 23 were woodworkers. The av age at the time of diagnosis was 55-60 yr, and the duration of exposure was 15-30 yr for 7, 30-40 yr for 7, and >40 yr for 3 patients; 6 were diagnosed after retirement. Most of the woodworkers were exposed to wood dust. (no refs)

79-5972 A Multicenter Inquiry into the Etiology of Pancreatic Diseases. (Eng) Sarles, H. (INSERM U 31, 46 Chemin de la Gaye, F-13009 Marseille, France); Cros, R. C.; Bidart, J. M. *Digestion* 19(2): 110-125; 1979.

The etiology of pancreatic diseases and the diet of patients with these diseases were surveyed with the collaboration of 36 centers in 19 countries having widely different climatic and racial conditions. A total of 2,478 patients were studied: 222 men and 208 women with acute pancreatitis (AP), 801 men and 134 women with calcified chronic pancreatitis (CCP), 525 men and 155 women with noncalcified chronic pancreatitis (NCCP), 69 men and 14 women with pancreatic cancer, and 281 male and 62 female controls. With

regard to chronic pancreatitis, the 19 countries could be classified into 4 dietary groups. (1) Southern Europe: the diet is rich in carbohydrates, protein, and lipids; alcohol intake is primarily in the form of wine; and the pathology is dominated by CCP. There are fewer women than men with chronic pancreatitis. (2) Northern Europe, Argentina, and Chile: the diet is rich in protein and alcohol consumption is beer-based, and there is a distinct prevalence of AP and NCCP. The prevalence of men with chronic pancreatitis is less marked than that in southern Europe. (3) Japan: the diet is poor in lipids and there is a low frequency of CCP and NCCP. (4) Tropical countries with mixed races that can be divided into two subclasses: (a) India is characterized by a low-fat, low-protein diet; no alcoholism; a high frequency of CCP at an early age; (b) Brazil and South America are characterized by a very high alcohol intake in the form of whiskey and a high frequency of CCP. (32 refs)

79-5973 Lung Cancer in Iron Miners in Lorraine. 270 New Cases Observed from 1964-1977. (Fre) Anthoine, D. (Service de pneumologie, Centre medical Paul Spillmann, 54690 Lay Saint-Christophe, France); Lamy, P.; De Ren, G.; Braun, P.; Cervoni, P.; Petiet, G.; Schwartz, P.; Zuck, P.; Lamaze, R. *Arch Mal Prof* 40(1/2): 48-51; 1979.

Characteristics of the lung cancer observed in 270 iron miners of Lorraine, France during the period 1964-1977 are presented. The cancers were more likely to be discovered by screening than those of nonminers and the lesion was more likely to be distal in location. Other literature studies presenting statistics on the incidence of lung cancer in iron miners are reviewed. (4 refs)

79-5974 Malignant Mesotheliomas in a Small Village in the Anatolian Region of Turkey: An Epidemiologic Study. (Eng) Artvinli, M. (Dept. Chest Diseases, Hacettepe Univ., Sch. Medicine, Ankara, Turkey); Baris, Y. I. *J Natl Cancer Inst* 63(1): 17-22; 1979.

Epidemiologic and etiologic studies of malignant pleural mesotheliomas (MPM's) were performed in two small villages in

the Anatolian region of Turkey, Tuzkoy and Kizikoy (the latter was used as a control). People ≥ 25 yr of age were studied, 312 (145 men and 167 women) from Tuzkoy and 95 (45 men and 50 women) from the control village. The annual incidence of MPM in Tuzkoy was found to be 6.5 cases (22 cases/10,000 people). Several other respiratory disorders were detected as well. Although no type of asbestos could be found in or around Tuzkoy, the asbestiform mineral zeolite was found in soil samples from its roads and fields, in its building stones, and in lung tissues of the villagers. Chest x-rays revealed no cases of MPM or other respiratory abnormalities in the control group. No zeolite could be found in the control village. Therefore, zeolite is thought to be the cause of MPM and the other respiratory disorders in Tuzkoy. (14 refs)

79-5975 Pleural Asbestosis in Dock Workers. (Ger) Diwok, K. (Klinik fur Innere Medizin, Wilhelm-Pieck Univ., Ernst-Heydemann-Strasse 6, DDR-25 Rostock, E. Germany); Lutkeholter, G.; Wendel, H.; Schleue, E.; Mucke, H. *Z Gesamte Inn Med* 34(7): 76-77; 1979.

During the last 3 yr, 29 patients with pleural asbestosis were examined. Twenty-one of them had a history of occupational exposure to dust. The beginning of exposure was at least 15 yr ago, and the duration of exposure was 5-25 yr. Two bronchial carcinomas and one pleural mesothelioma were found, which emphasizes the increased risk of malignancy among asbestosis patients. (13 refs)

- 79-5976 Export of Proteins from Oocytes of *Xenopus laevis*. (Eng) Colman, A. (Dept. Biological Sciences, Univ. Warwick, Coventry CV4 7AL, England); Morser, J. *Cell* 17(3): 517-526; 1979.

Experiments designed to test the specificity of protein secretion by oocytes of *Xenopus laevis* are described. When human lymphoblastoid messenger RNA (mRNA) was microinjected into *X. laevis* oocytes, interferon titers rapidly reached a max inside the oocyte but accumulation of interferon continued in the incubation medium for at least 45 hr. If interferon protein was injected into oocytes, it was rapidly inactivated. Significantly, newly synthesized interferon but not injected interferon was found to be membrane-associated. Further experiments involving the coinjection of mRNA's coding for secretory proteins (guinea pig milk proteins and human interferon) and nonsecretory proteins (rabbit globin) revealed that only the secretory proteins were exported from the oocyte. Moreover, different proteins were exported at different rates. A distinct subclass of newly synthesized oocyte proteins of unknown function also accumulated in the incubation medium. Since the information encoded in the mRNA's of secretory proteins is sufficient to specify the synthesis, compartmentation, and secretion of these proteins, the oocyte may provide a complete system for the analysis of the secretory process. - 79-5977 Relationships among Purine Nucleoside Metabolism, Adenosine Triphosphate Catabolism, and Glycolysis in Human Erythrocytes. (Eng) Henderson, J. F. (Dept. Biochemistry, McEachern Lab., Univ. Alberta Cancer Res. Unit, Edmonton, Alberta T6G 2H7, Canada); Zombor, G.; Burrige, P. W.; Barankiewicz, G.; Smith, C. M. *Can J Biochem* 57(6): 873-878; 1979.

In human RBC incubated with both naturally occurring purine nucleosides and with a variety of purine nucleoside analogs, ATP catabolism was accelerated and lactate accumulation was increased. Tubercidin was a particularly potent inducer of ATP catabolism. In cells incubated with tubercidin, the major route of adenylate metabolism was deamination, whereas in cells incubated with deoxyglucose, the major route was dephosphorylation. (20 refs)

- 79-5978 Xanthine Oxidase Activity in Extracts from Contact-inhibited and Spontaneously Transformed Mouse Embryo Cells in Culture. (Eng) Clynes, M. M. (Dept. Zoology, Univ. Coll., Belfield, Dublin 4, Ireland); Shannon, M. F.; Hurley, M. P. *Biochem Soc Trans* 7(3): 524-525; 1979.

The spontaneously transformed mouse cell lines 3T12 (derived from BALB/c mouse embryos) and 3T6 (from noninbred Swiss mouse embryos) were found to have higher xanthine oxidase activity than their contact-inhibited normal counterparts, BALB/3T3 and 3T3 cells. Nonconfluent BALB/3T3 and 3T12 cells contained lower xanthine oxidase activity than did confluent cells. (13 refs)

- 79-5979 Effects of Proteases and Protease Inhibitors on the 4.5 S and 8 S Androgen Receptor. (Eng) Wilson, E. M. (Dept. Pediatrics, Sch. Medicine, Univ. North Carolina, Chapel Hill, NC 27514); French, F. S. *J Biol Chem* 254(14): 6310-6319; 1979.

The size of the cytoplasmic and nuclear androgen receptors from Sprague-Dawley rat ventral and dorsal prostate, dorsal prostate (Dunning) tumor, testis, epididymis, and seminal vesicle was determined by Sephadex G-200 chromatography and sucrose gradient centrifugation. The protease inhibitor diisopropyl fluorophosphate (DFP) was used to minimize receptor breakdown. An 8S-9S, 8S- to 106-A receptor (mol wt = 280,000 to 365,000; frictional ratio f/f_0 = 1.9 to 2.4) observed in unfractionated cytosol prepared in low ionic strength buffer with or without DFP was in equilibrium with a 4.5S-5S, 58-A form (mol wt = 117,000; f/f_0 = 1.8) observed at salt concentrations >0.1 M KCl. Receptor partially purified using $(\text{NH}_4)_2\text{SO}_4$ or phosphocellulose chromatography in the absence of DFP was present as smaller fragments of 3.6S, 37A and 3.0S, 23A. Similar fragments were generated from the 4.5S or 8S receptor by mild trypsin treatment. In addition, ventral prostate contained a DFP-insensitive enzyme that specifically converted the 4.5S, 58-A receptor to the 3.6S, 37-A fragment. The DFP-insensitive enzyme was partially inhibited by rabbit bile, and it appeared similar to the enzyme seminin, a secretory protein of human prostate. Androgen receptor isolated in the presence of DFP from nuclei labeled in vivo was predominantly 4.5S, 58 A, with smaller forms (37 and 23 A) appearing in the absence of DFP. The 4.5S, 58-A nuclear receptors were also in equilibrium with a large 8S form. Receptor breakdown by DFP-insensitive and -sensitive proteases appeared to be an in vitro phenomenon. Furthermore, the size of the androgen receptor was not significantly changed during receptor migration from cytoplasm to nucleus. (57 refs)

- 79-5980 Characterization and Biosynthesis of ω -Aminoacyl Amino Acids from Rat Brain and the C-6 Glioma Cell Line. (Eng) Bauer, K. (Abt. Biochemie, Max-Volmer-Institut, Technische Universität Berlin, Franklinstrasse 29, D-1000 Berlin 10, W. Germany); Salnikow, J.; de Vitry, F.; Tixier-Vidal, A.; Kleinkauf, H. *J Biol Chem* 254(14): 6402-6407; 1979.

Omega-Aminoacyl acids from rat brain and the C-6 glioma cell line were isolated and characterized. Extracts of the glial cell line and of rat brain were separated in an ion-exchange chromatography system fitted with a stream splitter and continuously monitored after alkaline hydrolysis and reaction with o-phthalaldehyde for amino acids and peptides. Amino acid analysis of the fractionated material before and after acid hydrolysis indicated the presence of several peptides. When the ω -amino acid-containing fractions were further analyzed, carnosine [N-(β -alanyl)histidine], homocarnosine [N $^{\alpha}$ -(γ -aminobutyl)histidine], N $^{\alpha}$ -(β -alanyl)lysine, and N $^{\alpha}$ -(γ -aminobutyl)lysine were detected in the rat brain extract. In the glioma cell extract, N $^{\alpha}$ -(β -alanyl)ornithine and N $^{\alpha}$ -(γ -aminobutyl)ornithine, but not the corresponding lysine derivatives, were identified in addition to carnosine and homocarnosine. When the glioma cells

were incubated with the radiolabeled precursors β -alanine, γ -aminobutyric acid, and ornithine, label was incorporated into these peptides. For the β -alanyl-radiolabeled material, cochromatography with the synthetic peptides carnosine and N^{α} -(β -alanyl)ornithine was demonstrated in several chromatographic systems, and after acid hydrolysis, [3 H] β -alanine was found to be a constituent amino acid. Although carnosine has been discussed as a putative neurotransmitter of the olfactory chemoreceptor neurons, these results demonstrate that carnosine and related peptides are not only present in the C-6 glial cell, but they are actively formed by these cells. - 79-5981 Transcription of Ti Plasmid-derived Sequences in Three Octopine-Type Crown Gall Tumor Lines. (Eng) Gurley, W. B. (Plant Disease Resistance Res. Unit, Agricultural Res., U.S. Dept. Agriculture, Madison, WI 53706); Kemp, J. D.; Albert, M. J.; Sutton, D. W.; Callis, J. *Proc Natl Acad Sci USA* 76(6): 2828-2832; 1979.

Transcription of tumor-inducing (Ti) plasmid-derived sequences was studied in two sunflower tumor lines and a tobacco tumor line induced by *Agrobacterium tumefaciens* strains 15955, B6, and B6-806, respectively. Total RNA isolated from the three octopine-type crown gall lines contained sequences homologous to specific regions of the Ti plasmid of *A. tumefaciens* strain 15955. A comparison of transcripts in these three tumor lines suggests that tumor cells transcribe various sequences within a sector of plasmid DNA of 13×10^6 daltons and that transcription may not be uniform across the plasmid-derived sequences (T-DNA). Transcription of T-DNA by octopine-type tumors occurred at four major sites. The levels of transcription occurring at three of these sites appeared to vary considerably among the three tumor lines. Part of this variability may reflect differences in the organization and copy number of T-DNA. One of the transcription sites mapped within a region of DNA with common sequence homology to all Ti plasmids. Varying amounts of transcript homologous to this region of T-DNA were present in all three tumor lines. It is suggested that transcription of these conserved sequences in the plant may have significance regarding the mechanism of tumorigenesis. (33 refs)

- 79-5982 Tumor-specific DNA Sequences in Shay's Granulocytic Sarcoma. (Jpn) Yokoyama, S. (Dept. Medicine, Showa Univ. Sch. Medicine, Tokyo, Japan); Tsuruoka, N. *Acta Haematol Jpn* 42(3): 347-356; 1979.

DNA-RNA hybridization experiments were conducted to detect unique DNA sequences in Shay's granulocytic sarcoma cells, which was used as a model of human leukemia. Repetitive sequences comprised 47% of the tumor cell DNA, nonrepetitive sequences 53%. At low C_{ot} , the hybridization of tumor DNA with 3 H-uridine-labeled tumor RNA was higher than the hybridization of normal liver DNA with 3 H-uridine labeled tumor RNA. This indicated that abnormal sequences were present in the repetitive base sequence of tumor DNA. Poly G-C sequences were increased in the repetitive sequences of the tumor DNA. Compared with normal cell DNA, there were no abnormal sequences in the nonrepetitive sequence of the tumor DNA. Since the sarcoma contained high levels of reverse transcriptase activity, it is suggested that the abnormal sequences found in the repetitive base sequences of the tumor DNA originated from viral sources. - 79-5983 Spontaneous Transformation and Prolonged In Vitro Maintenance of Fetal Mouse Glial Cells. (Fre) Coulomb, B. (Section de Biologie, Institut Curie, 26 rue d'Ulm, 75231 Paris Cedex 05, France); Levy, S.; Maunoury, R.; Markovits, P. *Bull Cancer (Paris)* 66(3): 229-234; 1979.

Six cell lines obtained from the whole brain, cortex, or brain stem of A/Jax or C3H mice on gestation day 14 were maintained in culture and tested regularly for tumorigenicity in nude or syngeneic mice. The cells retained their glial character for about 1 mo after seeding. All cells were tested by the immunoperoxidase method for the presence of glial fibrillary acidic protein (GFAP). When 10^6 cells were injected into nude, A/Jax, or C3H mice, only the 14A cell line from the whole brain of an A/Jax mouse induced tumors in the syngeneic strain. Transformation occurred in the 11th cell generation. GFAP was detected in 14A cells from the whole brain, including the tumor cells and the cortex cells, but not in the brain stem cells. (15 refs)

- 79-5984 Differentiation of Human Neuroblastoma Cells in Culture. (Eng) Littauer, U. Z. (Dept. Neurobiology, Weizmann Inst. Science, Rehovot, Israel); Giovanni, M. Y.; Glick, M. C. *Biochem Biophys Res Commun* 88(3): 933-939; 1979.

The neuronal properties of a human neuroblastoma cell line (CHP-134) were found to be modulated to a high degree as a function of time in culture, even without the use of external inducing agents. A membrane glycoprotein, approx mol wt 200,000, was modulated in concert with an active ionic flux in the presence of 2% dimethyl sulfoxide. Other neuronal properties, acetylcholinesterase and choline acetyltransferase activity, were also modulated but to a lesser extent. The activity of these enzymes was independent of inducing agents. The appearance of the membrane glycoprotein on the surface of both human and mouse neuroblastoma cells only under conditions of differentiation leads to the suggestion that it is directly involved with active Na^+ channels. The finding that the cultured CHP-134 cells, which maintained their tumorigenicity, also showed a high degree of neuronal characteristics suggests that the concept that highly differentiated cells lose their tumor potential should be reconsidered. - 79-5985 Diagnosis of Intraocular Tumors by the Radiophosphorus Test. (Ger) Schmitt, E. J. (Univ. Augenklinik Mainz, Mainz, W. Germany). *Klin Monatsbl Augenheilkd* 174(3): 408-410; 1979.

Experience with the use of the radiophosphorus test as an additional method for diagnosing intraocular tumors is reported. In 49 cases, there was a 90% agreement between the positive test results and the histological findings. (no refs)

- 79-5986 Inhibition of the Activity of DNA Polymerase α by 2',3'-Dideoxythymidine 5'-Triphosphate. (Eng) Ono, K. (Lab. Viral Oncology, Aichi Cancer Center Res. Inst., Chikusa-Ku, Nagoya 464, Japan); Ogasawara, M.; Matsukage, A. *Biochem Biophys Res Commun* 88(4): 1255-1262; 1979.

A low concentration (1 μ M) of 2',3'-dideoxythymidine 5'-triphosphate (ddTTP) strongly inhibited (>70%) the activity of DNA polymerase α from MOPC-104E mouse myeloma cells in the

presence of Mn^{2+} . This activity was not inhibited in the presence of Mg^{2+} , even with up to 50 μM ddTTP. The extent of inhibition could be increased by raising the pH of the reaction. The inhibition was found to be caused by competition between ddTTP and 2'-deoxythymidine 5'-triphosphate for the same substrate binding site on the enzyme. The K_i for ddTTP (0.035 μM) was much lower than the K_m for ddTTP (1.8 μM). These findings indicate that ddTTP can be used to identify DNA polymerase α and to study the mechanism of in vitro DNA synthesis. (13 refs)

79-5987 Stress and Coping Factors Influence Tumor Growth. (Eng) Sklar, L. S. (Dept. Psychology, Carleton Univ., Ottawa, Ontario K1S 5B6, Canada); Anisman, H. *Science* 205(4405): 513-515; 1979.

The effects of stress (escapable or inescapable shock applied for 6 sec at 1-min intervals, 1.1-3.3 hr/day, 1-10 days) and coping mechanisms on the development of tumors following sc injection of syngeneic P815 mastocytoma cells were studied using male DBA/2J mice. Mice exposed to only one session of inescapable shock 24 hr after tumor implantation showed significantly earlier tumor appearance ($p < 0.01$), greater tumor area ($p < 0.001$), and earlier mortality ($p < 0.001$) than nonshocked controls. Tumor size was significantly greater ($p < 0.001$) and tumor latency was significantly shorter ($p < 0.05$) among animals exposed to inescapable shock than among those able to escape shock; mortality was nonsignificantly earlier among the mice exposed to inescapable shock. Compared with mice exposed to inescapable shock for 5 or 10 consecutive days, those shocked for only 1 day showed significantly reduced tumor latency ($p < 0.001$), significantly increased tumor size ($p < 0.001$), and significantly reduced survival time ($p < 0.001$). The data support the hypothesis that stress is involved in the development of carcinoma. (14 refs)

79-5988 Demonstration of Low Density Lipoprotein Receptors in Mouse Teratocarcinoma Stem Cells and Description of a Method for Producing Receptor-deficient Mutant Mice. (Eng) Goldstein, J. L. (Dept. Molecular Genetics, Univ. Texas Health Science Center, Dallas, TX 75235); Brown, M. S.; Krieger, M.; Anderson, R. G.; Mintz, B. *Proc Natl Acad Sci USA* 76(6): 2843-2847; 1979.

An attempt was made to devise a practical scheme for producing, from developmentally versatile mouse teratocarcinoma stem cells, whole-animal models with lesions comparable to familial hypercholesterolemia, a human genetic disorder that entails a deficiency in the specific cell-surface receptor that binds low-density lipoprotein (LDL) with a consequent alteration in the control of cholesterol metabolism. This requires first learning whether the tumor stem cells in culture express LDL receptors and then establishing a selection or screening procedure to identify receptor-deficient mutants in mutagenized cell cultures. The results show that the teratocarcinoma cells do in fact have specific high-affinity LDL receptors that are similar to those reported for fibroblasts and the parenchymal cells of specialized tissues and different from those of phagocytic cells. Sterols suppressed the otherwise efficient binding, internalization, and degradation of LDL (^{125}I -labeled) by the cells. Acetylation of LDL blocked the binding. Only LDL and not high-density lipoprotein (HDL) was bound. After LDL uptake and degradation, the liberated cholesterol led, as expected, to increased cholesteryl ester formation; it also suppressed the activity of 3-hydroxy-3-methylglutaryl coenzyme A reductase, the rate-limiting step in cholesterol biosynthesis. Cells with LDL receptors

were readily visualized by exposing them to a fluorescent derivative of LDL; in the fluorescence microscope, labeling was seen in all cells. Cells with experimentally depressed receptors, yielding little fluorescence, were separable from those with normal fluorescence. Thus, two methods for isolating receptor-deficient cells from mutagenized cultures are now available, either by visual recognition of low-fluorescing or nonfluorescing colonies in culture plates or by electronic cell sorting. Such mutants in an appropriate line of teratocarcinoma cells can then be passaged into blastocysts for full somatic tissue differentiation and germ-line development into mice. (26 refs)

79-5989 Teratocarcinoma Stem Cells Have a Cell Surface Carbohydrate-binding Component Implicated in Cell-Cell Adhesion. (Eng) Grabel, L. B. (Dept. Anatomy, Univ. California, San Francisco, CA 94143); Rosen, S. D.; Martin, G. R. *Cell* 17(3): 477-484; 1979.

The presence of a carbohydrate-binding component on the surface of teratocarcinoma (TC) stem cells was demonstrated. TC stem cells maintained in the undifferentiated state expressed a carbohydrate-binding component that recognized oligomannosyl residues. This cell-surface molecule was detected by a rosette assay in which the stem cells formed rosettes with glutaraldehyde-fixed trypsinized rabbit RBC. Addition of simple sugars to the assay mixture had little effect, but rosette formation was inhibited by a series of mannose-rich glycoproteins (yeast invertase, yeast mannan, and horseradish peroxidase). Periodate oxidation eliminated the inhibitory activity of invertase, whereas pronase digestion had little effect, indicating that carbohydrate moieties are essential for inhibition. Invertase and its glycopeptide derivatives also inhibited the reaggregation of dispersed stem cells and promoted the dissociation of preformed aggregates. These results suggest that intercellular adhesion of TC stem cells may be the consequence of the interaction of a lectinlike component detected in the rosette assay with a complementary oligosaccharide receptor on adjacent cells. (38 refs)

79-5990 The Differentiation of Teratocarcinoma Stem Cells Is Marked by the Types of Collagen Which Are Synthesized. (Eng) Adamson, E. D. (Dept. Zoology, Univ. Oxford, South Parks Road, Oxford, OX1 3PS, England); Gaunt, S. J.; Graham, C. F. *Cell* 17(3): 469-476; 1979.

Collagen synthesis was studied in a cloned line of undifferentiated teratocarcinoma cells (OC15S1) maintained as a homogeneous embryonal carcinoma (EC) cell population or cultured under conditions in which the cells differentiated into endodermlike (END) cells. Cell cultures were incubated with tritiated proline and lysine, and the radioactive collagen secreted into the medium was extracted and purified or immunoprecipitated by antibodies to type IV collagen. Radioactive collagens were identified by electrophoretic mobility, sensitivity to collagenase and to reduction, insensitivity to pepsin, cyanogen bromide peptides, and by amino acid analyses of 3-hydroxyproline, 4-hydroxyproline, and proline. OC15S1 EC cells synthesized several collagenous polypeptides, 60%-70% of which were like that of basement membrane (type IV) collagen. Type I-like collagen was the main collagenous product of END cells, but a minor product of EC cells. It was concluded that type IV collagen synthesis was suppressed during the differentiation of EC cells to END, but type I-like synthesis was increased. Similarly, other EC cell lines produced mainly type IV-like collagen polypeptides (PC13, F9, PSA1); following the formation of

END cells, two lines produced mainly type I-like collagen polypeptides (PC13, C145b). The type of endoderm formed on embryoid bodies, however, presents an alternate route of differentiation, since immunoperoxidase tests showed that it was synthesizing significant amounts of type IV collagen. (35 refs)

- 79-5991 Comparison of a Human Tumor Cell Line Before and After Growth in the Nude Mouse. (Eng) Fogh, J. (Human Tumor Cell Lab., Sloan-Kettering Inst. Cancer Res., Rye, NY); Bean, M. A.; Bruggen, J.; Fogh, H.; Fogh, J. M.; Hammar, S. P.; Kidera, Y.; Loveless, J. D.; Sorg, C.; Wright, W. C. In: *The Nude Mouse in Experimental and Clinical Research*. Fogh, J.; Giovanella, B. C., eds. (New York: Academic Press): 502 pp.; 215-234; 1978.

Several investigators participated in a study of the MeWo human melanoma cell line before and after passage in the nude mouse. Cells from a cultured line (NuCuMeWo) established after passage of the MeWo tumor were identical in morphology, ultrastructure, growth pattern, growth rate, susceptibility to poliovirus, and isozyme phenotypes to the original MeWo tumor. The modal chromosome number (44) was also the same before and after passage in the nude mouse, and various chromosome abnormalities were present in both MeWo and NuCuMeWo cells. The tumor histopathologies of both lines were similar, as were their tumor-producing capabilities in nude mice. As target cells in human lymphocyte-mediated cytotoxicity assays, MeWo and NuCuMeWo behaved similarly; in immune adherence tests, the two cell lines were similar but not identical. Thus, it appears that human tumor cell lines can be grown in vivo in the nude mouse and then again in vitro with little change in various parameters. (40 refs)

- 79-5992 Aging of Melanocytes. (Eng) Hu, F. (Div. Cutaneous Biology, Oregon Regional Primate Res. Center, Beaverton, OR 97005). *J Invest Dermatol* 73(1): 70-79; 1979.

The aging of choroidal melanocytes was studied using the eyes from rhesus monkey (*Macaca mulatta*) fetuses, neonates, infants, adolescents, young adults, and old adults. Melanocytes from biopsy samples of human lentigo simplex, lentigo senilis (LS); multiple lentiginos syndrome (MLS); nevus spilus (NS); junctional (JN), compound, and id nevus (IN); lentigo maligna (LM); and superficial malignant melanoma were also studied. With advancing age, the choroidal melanocytes showed the following changes: a tendency for the melanosomes to fuse into complexes; uneven melanization; melanolysosomes in the form of vacuoles containing irregular fibrillary or myelinlike lamellated membranes; and lipidlike granules completely or partially filled with homogeneous material of minimal electron density. The percentage of melanocytes with such changes was 10%-15% at 7 yr, 50% at 13 yr, and >60% at 15 yr. LS tissues showed a slight elongation of the rete ridges, an increase in the concentration of melanocytes in the basal layer, an increase in the amount of melanin in the melanocytes and basal keratinocytes, and melanin-containing macrophages in the dermis. In the tissue of MLS or NS, there were, in addition, a few giant melanosome complexes containing up to hundreds of melanosomes bound by a single membrane. These changes were exaggerated in LS. The ultrastructure of JN cells was similar to that of melanocytes in lentiginos. In IN, the nevus cells immediately below the dermoepidermal junction resembled JN cells, but deeper in the dermis they lost their proliferative and melanogenic activity. A wide variety of changes was

seen in LM melanosomes, many of the changes being similar to those seen in lentiginos. The data show that ultrastructural changes in melanosomes of postmitotic, fully differentiated choroidal melanocytes are quantitatively and qualitatively related to aging. (21 refs)

- 79-5993 Evidence for Removal at Different Rates of O-Ethyl Pyrimidines and Ethylphosphotriesters in Two Human Fibroblast Cell Lines. (Eng) Bodell, W. J. (Dept. Molecular Biology, Univ. California, Berkeley, CA 94720); Singer, B.; Thomas, G. H.; Cleaver, J. E. *Nucleic Acids Res* 6(8): 2819-2829; 1979.

The extent of removal and the relative persistence of O-ethylpyrimidines and ethylphosphotriesters (EPT) from replicating normal (GM637) and xeroderma pigmentosum (XP-12 RO) cells were investigated in an attempt to learn more about the specificity and diversity of enzymes acting presumably as glycosylases or dealkylases. Seven ethyl derivatives were induced in these cells by using ¹⁴C-ethylnitrosourea, and their removal and persistence were assayed chromatographically. Both GM637 and XP-12 RO fibroblasts had similar abilities to remove ethyl products (approx 34% and 27% were lost from these cells, respectively), except for O⁶-ethylguanine (OEG), which persists longer in the XP-12 RO cells. The absolute amounts of O²-ethylthymine (O²-ET), (O⁴-ET), and O²-ethylcytosine (OEC) were decreased in cellular DNA after correction for cell growth. The rate of decrease diminished after approx 20 hr, and 20%-40% of each derivative persisted after more than two cell doublings. Because these derivatives are stable in isolated DNA, the decreases observed in vivo are attributed to enzymatic activity. The unstable purine derivatives 7-ethylguanine and 3-ethyladenine were removed from cellular DNA at a faster rate than they disappeared in vitro, and this rate cannot be accounted for by the lability of the glycosyl bond. Again, the results imply enzyme activity in the removal of these derivatives. The amount of EPT remained almost unchanged during 72 hr of cell culture, implying that their removal involves a unique mechanism. The persistence of O²-ET, O⁴-ET, OEC, and OEG may be explained in at least two ways: (1) an enzyme capable of removing alkyl products is present or induced in early replication and is no longer active after a certain period of time, or (2) the protected alkyl derivatives are in a chromatin subfraction protected from enzymes and excised either more slowly or not at all. Their persistence during replication and transcription may represent initiating events in carcinogenesis. (39 refs)

- 79-5994 The Influence of Implantation Site on Tumor Growth and Blood Flow. (Eng) Young, S. W. (Dept. Radiology, Stanford Univ. Medical Center, Stanford, CA 94305); Hollenberg, N. K.; Abrams, H. L. *Eur J Cancer* 15(5): 771-777; 1979.

A study was made of the differences in tumor growth and their relationship to tumor blood flow in several different tissues. A suspension of V2 carcinoma cells was implanted in the liver, spleen, kidney, testicle, and ear of 34 New Zealand white rabbits. Two weeks after implantation, blood flow in the tumor and surrounding normal host tissue was determined with radioactive microspheres. Total tumor wt was found to be related to the site of implantation: liver (8.7 g), spleen (8.4 g), kidney 2.9 g, testicle (1.2 g), and ear (0.4 g). The amount of gross caseous necrosis in the V2 carcinoma was also related to implantation site. The organ with the largest proportion of grossly nonnecrotic tumor was the

liver (5% necrotic) and that with the least was the spleen (62% necrotic). V2 blood flow also varied with implantation site, the highest flow being found in the kidney (1.3 ml/g/min) and the lowest in the ear (0.14 ml/g/min). Regression analysis revealed that tumor blood flow was directly related to resting blood flow in the surrounding host parenchyma. However, no relationship existed between tumor perfusion and either tumor size or the amount of central necrosis. (22 refs)

- 79-5995 Flow Cytometry of Isolated Nuclei Prepared from 9L Rat Brain Tumor. (Eng) Hoshino, T. (Brain Tumor Res. Center, Dept. Neurological Surgery, Univ. California, 350 Parnassus Ave., Suite 807, San Francisco, CA 94143); Gray, J. W.; Nomura, K. *Lab Invest* 41(1): 72-76; 1979.

A modification of a previously reported nucleus isolation procedure is described in detail. Nuclei isolated by grinding 9L rat brain tumors gave a DNA distribution consisting of a diploid (2C) DNA peak due to noncycling normal cells and a bimodal distribution beginning at about 4C DNA due to cycling tumor cells. Autoradiographic studies of nuclei from rats that received a pulse of ^3H -thymidine in vivo confirmed that the majority of proliferating cells were in the bimodal part of the distribution. The fraction of cells in the S phase, determined from the DNA distributions, was 15.3%. This is consistent with a labeling index of 18%, determined from autoradiographs of tumor tissue, and an S-phase fraction of 17%, determined by analysis of a fraction of labeled mitosis (assuming that all of the 53% noncycling cells are in G_0). Autoradiographic analysis of cells sorted from the tumor's mid-S-phase region showed that only 58% of these cells were labeled. This is attributed mostly to the presence of fluorescent debris from necrotic nuclei in this part of the distribution. (17 refs)

- 79-5996 Population Analysis of the DNA Content in Adenocarcinoma Cells by Means of Flow Micro-Fluorometry. (Eng) Nishiya, I. (Dept. Obstetrics and Gynecology, Sch. Medicine, Hokkaido Univ., Sapporo, Japan); Ishizaki, Y. *Proc Japan Acad., Series B: Phys & Biol Sci* 55(2): 53-57; 1979.

Cellular DNA levels in 3 cases of undifferentiated cervical adenocarcinoma (AC), 6 cases of moderately differentiated endometrial AC, and 3 cases of serous ovarian cystadenocarcinoma were studied by rapid flow microfluorometry. All three cervical and five of the endometrial AC's demonstrated two peaks: the second peak arose in the diploid area and the first arose in the tetraploid to hexaploid ranges. The ovarian cystadenocarcinomas showed a narrow, sharply pointed peak in the diploid range. At the same time, there was a wide distribution among the samples ranging from the tetraploid to the hexaploid areas. (8 refs)

- 79-5997 Inhibition of Mammary Tumorigenesis in GR Mice with 2-Bromo- α -ergocryptine. (Eng) Welsch, C. W. (Dept. Anatomy, Michigan State Univ., E. Lansing, MI 48824); Goodrich-Smith, M.; Brown, C. K.; Wilson, M. *Int J Cancer* 24(1): 92-96; 1979.

An attempt was made to determine if prolactin is a contributing hormone in the genesis of mammary tumors in GR mice. In one series of experiments, 238 15-wk-old nulliparous GR mice were

treated with estrone (0.5 mg/liter drinking water) plus progesterone (30-mg pellet with cholesterol, implanted sc once monthly) for 13 wk. Half of these mice were inoculated sc once daily with 100 μg of the prolactin-suppressing drug 2-bromo- α -ergocryptine (CB-154) for the duration of hormone treatment, and the other half were inoculated sc once daily with 0.9% NaCl soln (controls). In another series of experiments, 87 pregnant GR mice were divided into two groups and inoculated sc once daily from days 7 to 21 of pregnancy with 0.9% NaCl soln (controls) or CB-154 (100 μg /mouse). In the first series, the number of mice with mammary tumors and the total number of mammary tumors were: controls, 58/119 and 73; CB-154-treated, 34/119 and 37, respectively. In the second series, the numbers were: controls, 39/44 and 73; CB-154-treated, 24/43 and 43, respectively. In both studies, CB-154 treatment significantly reduced the percentage of mice with mammary tumors and the total number of mammary tumors ($p < 0.05$ - 0.005). These results provide evidence that prolactin contributes to the genesis of estrone/progesterone- and pregnancy-induced mammary tumors in female GR mice. (31 refs)

- 79-5998 Ceruloplasmin Elevation and Synthesis in Rats with Transplantable Tumors. (Eng) Linder, M. C. (Dept. Chemistry, California State Univ., Fullerton, CA 92634); Bryant, R. R.; Lim, S.; Scott, L. E.; Moor, J. E. *Enzyme* 24(2): 85-95; 1979.

Plasma ceruloplasmin (CP) levels were measured in adult female rats of three strains with various transplantable tumors. Ceruloplasmin oxidase (CO) activity in the plasma of most tumor-bearing rats was significantly elevated over that in controls by 25%-200%. The degree of elevation showed some correlation to tumor size, especially in the case of the larger tumors, and elevations were not evident in animals with one of the slowest growing tumors. Removal of the adrenal glands did not modify the effect of tumor implantation on CO levels. Within 6 days after implantation of the fast-growing tumor line DMBA-5A, CP activity was increased an additional 50% by 21 days. The elevation in CO activity was accompanied by an increase in plasma copper concentrations. Both CO and copper increased to the same degree in the initial phase of tumor growth; however, CO activity continued to increase as the tumors grew much larger, whereas copper did not. The incorporation of (^3H)leucine into all plasma protein classes was depressed in the tumor-bearing animals, but the incorporation into CP was increased appreciably. The state of activation of CP from tumor-bearing rats was greater than that of CP from normal controls. CP activation was well correlated with CO activity in individual rats with mammary tumors. (19 refs)

- 79-5999 Clinical and Pharmacological Implications of Cancer Cell Differentiation and Heterogeneity. (Eng) Calabresi, P. (Dept. Medicine, Brown Univ., Roger Williams General Hosp., 825 Chalkstone Ave., Providence, RI 02908); Dexter, D. L.; Heppner, G. H. *Biochem Pharmacol* 28(12): 1933-1941; 1979.

Various aspects and interrelationships of intraneoplastic diversity were investigated at two levels: (1) differences among multiple subpopulations of tumor cells at any point in time (heterogeneity) and (2) variations among these subpopulations as a result of their maturation with time (differentiation). Cancer cells obtained from BALB/c/c3H murine mammary tumors and a transplantable rhabdomyosarcoma passaged in CE/J mice, as well as from two

patients with carcinoma of the colon were used. Several cell lines of these tumors were cloned and characterized. Neoplastic cell differentiation was induced by the polar solvent N,N-dimethylformamide (DMF). Differentiation was evidenced by morphological maturation, conversion of tumor cell markers and cell culture characteristics to those consistent with a more benign phenotype, and loss of tumorigenicity. Striking morphological and biological heterogeneity was observed in neoplastic subpopulations isolated from a single tumor, including marked variability in growth potential, surface antigens, and sensitivity to chemotherapeutic agents. The ability to dissect and analyze tumor cell heterogeneity in human cancer with this methodology offers a unique opportunity to delve into the clinical and pharmacological implications of tumor substructure. 79-6000 Glycoproteins of Cultured Epithelial Cells from Human Colonic Adenocarcinoma and Fetal Intestine. (Eng) Kim, Y. S. (Gastrointestinal Res. Lab., Veteran Admin.

Hosp., 4150 Clement St., San Francisco, CA 94121); Whitehead, J. S.; Perdomo, J. *Eur J Cancer* 15(5): 725-735; 1979.

The mol wt distribution and Concanavalin A binding properties of labeled glycopeptides and glycoproteins from cell surface membranes, cytoplasmic fractions, and culture media were studied in human fetal and neoplastic colonic cells. The cells were cultured in the presence of [^{14}C]- or [^3H]-labeled glucosamine or fucose. Both fucose and glucosamine were incorporated into the membrane glycoprotein fraction of colonic adenocarcinoma cells to a much lesser extent than into fetal cells. The elution profile obtained from Bio-gel P-150 column chromatography indicated that colonic cancer cell membranes contained fucose- and glucosamine-labeled, trypsin labile, high mol-wt glycopeptides not present in fetal cells. Affinity chromatographic studies of membrane glycopeptides using agarose-bound Concanavalin A indicated that cell membranes from fetal and colonic cancer cells contained not only glycoproteins of different mol wt, but glycoproteins having different oligosaccharide side chains. These results indicate that there are significant quantitative and qualitative differences in cell surface glycoproteins between fetal and cancerous intestinal cells. (29 refs)

Subject Index

Abnormalities

- Ethane, 1,2-Dibromo-Spermatzoa, 79-5521
- Hepatosoma
 - Kidney, 79-5916
- Radiation, Ionizing
 - Mutagenic Activity, 79-5689
- 4,4'-Stilbenediol, α,α' -Diethyl-
 - Urogenital System, Rat, 79-5667
- Acetamide, *N*-(Acetyloxy)-*N*-fluoren-2-yl-
 - Ames Test
 - Structure-Activity Relationship, 79-5617
 - DNA Repair
 - Mutagenic Activity, 79-5617
- Acetamide, *N*-(Acetyloxy)-*N*-(4-(2-phenylethenyl)phenyl)-Adenosine
 - Cytidine, 79-5554
 - Cytidine
 - Nucleoside Adducts, 79-5554
 - Guanosine
 - Nucleoside Adducts, 79-5554
 - Nucleic Acids
 - Alkylation Reactions, 79-5555
 - Nucleoside Adducts, 79-5555
 - Polynucleotides
 - Alkylation Reactions, 79-5555
- Acetamide, *N*-Fluoren-2-yl-
 - Alpha Fetoproteins
 - Hepatotoxicity, 79-5552
 - Ames Test
 - S9 Fraction, 79-5629
 - 5,6-Benzoflavone
 - Metabolism, Liver, 79-5551
 - Endonucleases
 - Ultraviolet Rays, 79-5628
 - Hepatosoma
 - Piperonyl Butoxide, 79-5553
 - Precancerous Conditions, Review, 79-5489
 - Phenol, *p*-Nitro-
 - Metabolism, Liver, 79-5551
- Acetamide, *N*-Fluoren-3-yl-
 - Microsomes, Liver
 - Metabolism, 79-5556
- Acetamide, *N*-Fluoren-2-yl-di-
 - Hepatosoma
 - Growth, Review, 79-5407
- Acetamide, *N*-(9-Hydroxyfluoren-3-yl)-
 - Microsomes, Liver
 - Metabolism, 79-5556
- Acetamide, *N*-(9-Oxofluoren-3-yl)-
 - Microsomes, Liver
 - NADH, NADPH Oxidoreductases, 79-5556
- Acetanilide, 4'-(*p*-Fluorophenyl)-
 - Hepatosoma
 - Growth, Review, 79-5407
- Acetanilide, 4'-Phenyl-
 - Hepatosoma
 - Piperonyl Butoxide, 79-5553
- Acetic Acid, (2,4-Dichlorophenoxy)-
 - Occupational Hazard
 - Herbicides, Review, 79-5413
- Acetic Acid, Methylnitrosaminomethyl Ester
 - Gastrointestinal Neoplasms
 - Administration Route, Rat, 79-5550
 - Lung Neoplasms
 - Adenocarcinoma, 79-5550
 - Mammary Neoplasms, Experimental
 - Adenofibroma, 79-5550
 - Nervous System Neoplasms
 - Neurilemmoma, 79-5550

- Acetic Acid, Methylnitrosaminomethyl Ester (cont'd)
 - Neurilemmoma
 - Administration Route, Rat, 79-5550
 - Sebaceous Gland Neoplasms
 - Zymbal Gland, 79-5550
- Acetohydroxamic Acid, *N*-4-Biphenyl-
 - Piperonyl Butoxide
 - Hepatocarcinogenicity, 79-5553
- Acetohydroxamic Acid, *N*-Fluoren-2-yl-
 - Ames Test
 - Mutagenic Metabolite, 79-5551
 - Piperonyl Butoxide
 - Hepatocarcinogenicity, 79-5553
- p*-Acetophenetidine
 - Kidney Neoplasms
 - Carcinoma, Transitional Cell, 79-5612
- Acetophenone, 2-Amino-
 - Adrenal Gland Neoplasms
 - Carcinogenic Activity, Hamster, 79-5673
 - Granulosa Cell Tumor, 79-5673
 - Bladder Neoplasms
 - Adenoma, 79-5673
 - Carcinoma, 79-5673
 - Lung Neoplasms
 - Carcinoma, Epidermoid, 79-5673
 - Ovarian Neoplasms
 - Granulosa Cell Tumor, 79-5673
 - Testicular Neoplasms
 - Disgerminoma, 79-5673
- Acetylcholinesterase
 - Neuroblastoma
 - Cells, Cultured, 79-5984
- Acetylglucosaminidase
 - Laryngeal Neoplasms
 - Lymphocytes, 79-5844
- Acid Phosphatase
 - Virus, SV40
 - Lysosomes, 79-5805
- Acrylamide, 2-(2-Furyl)-3-(5-nitro-2-furyl)-
 - L Cells
 - DNA Replication, 79-5585
- Actin
 - Cell Transformation, Neoplastic
 - Mouse, Nude, Review, 79-5469
 - Virus, Murine Sarcoma
 - Protein Kinase, 79-5729
- Adelphane
 - Antihypertensive Agents
 - Chromosome Aberrations, 79-5611
 - Chromosome Aberrations
 - Mitosis, 79-5611
- Adenine, 3-Methyl-
 - Urea, Methyl Nitroso-
 - DNA Repair, 79-5567
- Adenocarcinoma
 - Bone Neoplasms
 - Wood, 79-5971
 - Colonic Neoplasms
 - Glycoproteins, 79-6000
 - Esophageal Neoplasms
 - Epidemiology, Nigeria, 79-5961
 - Esophagitis, Peptic, 79-5897
 - Fucose
 - Membrane Proteins, 79-6000
 - Gastrointestinal Neoplasms
 - Epidemiology, France, 79-5967
 - Gynecologic Neoplasms
 - DNA, 79-5996
 - Epidemiology, 79-5953
 - Intestinal Neoplasms
 - Methanol, (Methyl-*ONN*-azoxy)-, Acetate (Ester), 79-5516

- Adenocarcinoma (cont'd)
 - Morpholine, *N*-Nitroso-, 79-5593
- Kidney Neoplasms
 - Erythropoietin, 79-5914
 - 1-Propanol, 2,3-Dibromo-, Phosphate, 79-5531
- Kidney Transplantation
 - Case Report, 79-5846
- Lung Neoplasms
 - Acetic Acid, Methylnitrosaminomethyl Ester, 79-5550
 - Amylases, 79-5890
 - Cholanthrene, 3-Methyl-, 79-5642
 - Hydrazine, 4-Hydroxymethylphenyl-, 79-5549
 - Immunity, Cellular, 79-5845
 - Iron, 79-5892
 - Neoplasm Metastasis, 79-5914
 - Occupational Hazard, 79-5892
 - Smoking, 79-5963
 - Transplantation, Heterologous, 79-5914
- Mammary Neoplasms, Experimental
 - Epiglycanin, 79-5847
 - Epiglycanin, Isolation and Characterization, 79-5848
- Petroleum
 - Transplantation, Heterologous, 79-5832
- Polycythemia
 - Erythropoietin, 79-5914
 - Transplantation, Heterologous, 79-5914
- Rectal Neoplasms
 - Genetics, 79-5899
- Stomach Neoplasms
 - Guanidine, 1-Propyl-3-nitro-1-nitroso-, 79-5591
 - Hermans' Syndrome, 79-5842
- Wood
 - Occupational Hazard, 79-5971
- Adenofibroma
 - Breast Diseases
 - Theophylline, 79-5596
 - Breast Neoplasms
 - Contraceptives, Oral, 79-5440
 - Mammary Neoplasms, Experimental
 - Acetic Acid, Methylnitrosaminomethyl Ester, 79-5550
- Adenoma
 - Adrenal Gland Neoplasms
 - Cushing's Syndrome, 79-5666
 - Testosterone, 79-5666
 - Bladder Neoplasms
 - Acetophenone, 2-Amino-, 79-5673
 - Intestinal Neoplasms
 - Cell Transformation, Neoplastic, 79-5902
 - Genetics, 79-5902
 - Methanol, (Methyl-*ONN*-azoxy)-, Acetate (Ester), 79-5516
 - Morpholine, *N*-Nitroso-, 79-5593
 - Polyps, 79-5906
 - Intestinal Polyps
 - Cell Transformation, Neoplastic, 79-5902
 - Kidney Neoplasms
 - 1-Propanol, 2,3-Dibromo-, Phosphate, 79-5531
 - Liver Neoplasms
 - Contraceptives, oral, 79-5441, 79-5443
 - Lung Neoplasms
 - Benz(a)anthracene, 7,12-Dimethyl-, 79-5553
 - Cholanthrene, 3-Methyl-, 79-5642
 - Hydrazine, 4-Hydroxymethylphenyl-, 79-5549
 - Ultrastructural Study, 79-5891
 - Urea, 1-(2-Chloroethyl)-3,3-diethyl-1-nitroso-, 79-5571
 - Urea, 1-(2-Chloroethyl)-3,3-dimethyl-1-nitroso-, 79-5571

- Adenoma (cont'd)**
 Urea, Ethyl Nitroso-, 79-5891
 Urea, 1,3,3-Tris(2-chloroethyl)-1-nitroso-, 79-5571
- Parathyroid Neoplasms**
 Neoplastic Endocrine-Like Syndromes 79-5868
- Pituitary Neoplasms**
 Prolactin, 79-5595
 Somatotropin, 79-5595
- Prolactin**
 Theophylline, 79-5595
 Thyrotropin Releasing Hormone 79-5595
- Somatotropin**
 Ergocryptine, 2-Bromo-, 79-5595
 Theophylline, 79-5595
 Thyrotropin Releasing Hormone 79-5595
- Stomach Neoplasms**
 Guanidine, 1-Propyl-3-nitro-1-nitroso- 79-5591
- Adenoma, Eosinophilic**
 Pituitary Neoplasms
 Neurofibromatosis, 79-5869
- Adenomatosis, Familial Endocrine**
 Gastrointestinal Neoplasms
 Peptides, Review, 79-5483
 Pituitary Neoplasms
 Case Report, 79-5870
 Thyroid Neoplasms
 Case Report, 79-5870
- Adenosine**
 Acetamide, *N*-(Acetyloxy)-*N*-(4-(2-phenylethenyl)phenyl)-
 Cytidine, 79-5554
- Adenosine Cyclic 3',5' Monophosphate**
 Diethylamine, *N*-Nitroso-
 Protein Kinase, 79-5563
 12-*O*-Tetradecanoylphorbol-13-acetate
 Catecholamines, 79-5625
 Prostaglandins E, 79-5625
- Adenosine, *N*-Methyl-**
 Virus, SV40
 RNA, Messenger, 79-5796
 RNA, Viral, 79-5796
- Adenosine Triphosphatase**
 Liver Neoplasms
 Ethylene, Chloro-, 79-5528
- Adenosine Triphosphate**
 Glucose, 2-Deoxy-
 Erythrocytes, 79-5977
 Tubercidin
 Erythrocytes, 79-5977
 Virus, SV40
